6. A shuttle-body having an opening to receive a filling-carrier, laterally-separable holding-jaws for the latter at one end of said opening, and a resilient finger mounted on the shuttle-body above and between said jaws and extending toward the opposite end of the shuttle-body to enter and interiorly engage the tubular head of a filling-carrier when the latter is inserted between and held by the jaws, to steady the filling-carrier and maintain it in operative position.

697,714. CORNER-POST, TRANSDOM-BAR, OR MULLION. JAMES GOLDENHITTE, Columbus, Ohio, assignor to Maggie A. Graham, Columbus, Ohio. Filed Apr. 26, 1901. Serial No. 68,191. (No model.)

Claim.—1. In a window, a corner-post, transdom-bar, or mullion consisting of a bar of wood, a metallic angle-bar attached longitudinally thereto, a recess in the side of the wood portion to receive the edge of a glass plate or pane, and means to secure the glass in such recess.

2. In a window, a corner-post, transdom-bar or mullion of wood, a core of angle-bar of metal therein, a recess in the side of the wood portion to receive the edge of a glass plate or pane, and a stop to secure the glass in such recess.

3. In a window, a corner-post, transdom-bar or mullion of wood, a recess in the side of said wood portion to receive a glass plate or pane, and a flanged metallic bar having a flange embedded longitudinally in said wood portion, substantially as described.

697,715. CHURCH. JAMES M. HARTER, Chicago, Ill. Filed Feb. 8, 1902. Serial No. 66,696. (No model.)

Claim.—1. In a churn, a rotatable dasher-rod, a dasher carried thereby and having a propeller form, a stationary member arranged to

surround said dasher, and held in concentric relation therewith by a web or spider engaging the dasher-rod, an exterior projection on said annulus forming a step, a containing vessel, and means within said vessel for engaging said step.

2. In a churn, a reversible dasher-rod, a dasher carried thereby and having a propeller form, a stationary annulus arranged to surround said dasher, and held in concentric relation therewith by a web or spider, the hub of which is provided with a side opening to permit lateral disengagement, an exterior projection on the annulus forming a step, a containing vessel, and means within said vessel for engaging said step.

3. In a churn, the combination of a main cylindrical casing, a reversible dasher-rod arranged vertically therein, a dasher secured to the said rod, means for imparting rotary movement to the dasher, a pair of vertical plates or breaks arranged within the casing in diametrically-opposed relation, a pair of elastic conical connections cutting said breaks together, a stationary annulus co-spirally with the dasher, a spider on said annulus engaging the dasher-rod to maintain concentric relation between the parts, and a step on the exterior of each annulus for engagement with one of the vertical breaks to prevent a turning movement of each annulus, substantially as set forth.

697,716. APPARATUS FOR LOADING CARS, WAGONS, OR ALIEN F. HARRIS, Hudson, N. Y. Filed Oct. 7, 1901. Serial No. 77,988. (No model.)

Claim.—1. In a loader, the combination with a base and elevating-conveyor, of a shaker-board pivoted at one end in said base, the other end of the board being free, and means on the shaft of the conveyor engaging the said free end for agitating the said shaker-board.

2. In a loader, the combination with a base and elevating-conveyor, of a shaker-board mounted in said base, and adjustable guides secured on said board to direct the flow of material on said board.

3. In a loader, the combination with a base and an elevating-conveyor, of a shaker-board pivoted within said base and intermittently engaged by the conveyor.

4. In a loader, the combination with a base, a shaker-board pivoted within the same, guides pivotedly mounted on the upper face of said board and means adjustable on said board for holding the said guides in different positions.

5. In a loader, the combination with a base and an elevating-conveyor extending upwardly therefrom, of a shaker-board pivotedly mounted in said base and toothed wheels mounted on one of the shafts of the conveyor adapted to engage said shaker-board.

6. In a loader, the combination with a base and an elevating-conveyor extending upwardly therefrom, of a shaker-board pivotedly mounted in said base and extending in the path of the conveyor, guides pivotedly mounted on the upper face of said shaker-board, a series of openings in said board in the path of the free ends of said guides, pins adapted to be secured in said openings to hold the guides in the desired adjusted position, toothed wheels secured upon each end of the lower shaft of said conveyor adapted to engage the free end of the shaker-board, gang-planks hinged to each side of the base, and removable gang-planks bridging said base, means for supporting the conveyor in its elevated position, and means for operating said conveyor.

697,717. STREET-LAMP. JOHN C. HENNING and JAMES W. HENNING, Baltimore, Md., assignors of one-third to Richard H. Johns, Baltimore, Md. Filed Sept. 21, 1901. Serial No. 78,044. (No model.)

Claim.—1. In a lamp and in combination, a burner, a tank for supplying oil thereto, a globe and a reflector having a central opening, a draft-tube extending through the reflector, and a ring-clamp movable on the outer walls of the tube, freely seated upon the inner wall of the reflector closing the joint around its central opening and freely suspending said tube from the reflector.

2. In a lamp and in combination, a burner, a tank for supplying oil thereto, a chimney for the burner, a globe and a reflector having a central opening, a draft-tube extending through the reflector, means for adjustably suspending the tube from the reflector, said draft-tube being of greater diameter than the burner-chimney, telescoping with it and forming a draft between the outer walls of the chimney and the inner walls of the draft-tube.

697,718. LEVEL. THOMAS F. HENRY, Johnsonville, N. Y., assignor of one-half to Charles J. Van Wert, Johnsonville, N. Y. Filed June 12, 1901. Serial No. 64,311. (No model.)

Claim.—A level provided with a reliable chamber, a plumb-bob pivotedly supported therein and adapted to swing longitudinally of the level, a dial-plate on the top of the level, a pointer operating in connection therewith, said pointer being in operative connection with said plumb-bob, two segmental strips between which the lower end of the plumb-bob swings, and means for operating one of said strips so as to lock the plumb-bob in a stationary position, consisting of a revoluble screw mounted in the cover of the chamber a nut mounted on said screw and provided with a finger passing through an inclined slot formed in one of said segmental guide-strips, substantially as shown and described.

697,719. PIPE-LIFTING MACHINE. ARTHUR HARRISON, Colmar, Iowa. Filed Nov. 14, 1901. Serial No. 80,486. (No model.)

Claim.—1. In a pipe-lifting mechanism, the combination of an inverted-U-shaped frame, brackets secured thereto, a guide-rod secured in one of said brackets, and a lifting-lever pivoted between said brackets, guide-rollers journaled in front of said lifting-lever, said rollers increasing in diameter toward their rear ends, whereby the pipe is supported at its rear end, chains or cables connected to said lifting-lever, substantially as described.

2. In a pipe-lifting mechanism, the combination with a frame, and

pipe-lifting means of guide-rollers secured to said frame; the rear ends of said rollers being greater in diameter than the front ends, whereby pipes of a different diameter may be accommodated by said rollers substantially as described.

697,720. AUTOMOBILE. HENRY E. HARRIS, Chicago, Ill. Filed July 21, 1901. Serial No. 78,045. (No model.)

Claim.—1. In an automobile, the combination with the traction-wheel mounted on a stationary axle or bearing and having a pulley-wheel thereon, of a driving-shaft mounted in bearings movable relative to the traction-wheel bearings, a driving-pulley mounted thereon, a roller-disk secured to said shaft to rotate therewith in the plane of the traction-wheel, a belt or rope connecting said pulley-wheel, means for continuously rotating the driving-shaft, and means for moving the driving-shaft toward the traction-wheel so as to release the driving-belt and subsequently apply the roller-disk to the traction-wheel to reverse it.

2. In an automobile, the combination with the traction-wheel mounted on a stationary axle or bearing and having a pulley-wheel thereon, of a driving-shaft having a driving-pulley-wheel thereon and a reversing-disk in the plane of the traction-wheel, a belt connecting said pulley-wheel, means for driving said driving-shaft, a means for bringing the driving-shaft and traction-wheel toward each other so as to release the traction of the driving-belt and to apply the reversing-disk to the traction-wheel.

3. In an automobile, the combination with the power-shaft, of a counter-shaft having driving-pulleys thereon, levers for the counter-shaft adapted to swing about the axis of the power-shaft, driving connections from the power-shaft to the counter-shaft, traction-wheels having driven pulleys, and a band from each driving-pulley to its associated driven pulley.

4. In an automobile, the combination of a power-shaft, a through-shaft having driving-pulleys, levers for the through-shaft adapted to swing about the axis of the power-shaft, a chain from the power to the through-shaft, traction-wheels having driven pulleys, and a band from each driving-pulley to its associated driven pulley.

5. In an automobile, in combination a driving and driven pulley having a band, a combined band and reverse disk associated with the driving-pulley, means to move the said pulley to slack the band and cause the disk to lay upon the traction-wheel.

697,721. SELF-LUBRICATING PULLEY. CHARLES J. HUNT and EDWARD E. LAMBERT, Dayton, Ohio. Filed Aug. 20, 1901. Serial No. 78,057. (No model.)

Claim.—1. In a self-lubricating pulley the combination with the pulley made in sections transversely of its axis with a portion of the hub on each section, an oil-chamber within the pulley and on the outer side of the hub, and the adjacent ends of said hub-sections formed with an annular oil-passage between them, a portion of said annular passage extending parallel with the axis of the pulley, of an annular chamber in the said portion of the passage parallel with the axis and an annular pervious packing located in said chamber and bridging the passage; substantially as described.

2. In a self-lubricating pulley, the combination with the pulley made in sections transversely of its axis with a portion of the hub on each section, an oil-chamber within the pulley and on the outer side of the hub, and the adjacent ends of said hub-sections formed with an annular oil-passage between them, a portion of said annular passage extending parallel with the axis of the pulley, of an annular pervious packing located in an enlargement of said passage, remote from the inner end of the passage; substantially as described.

3. In a self-lubricating pulley the combination with the pulley made in sections transversely of its axis with a portion of the hub on each section, an oil-chamber within the pulley and on the outer side of the hub, and the adjacent ends of said hub-sections formed with an annular oil-passage between them, a portion of said annular passage extending parallel with the axis of the pulley, of an annular chamber in the said portion of the passage parallel with the axis and an annular pervious packing located in said chamber and bridging the passage; substantially as described.

4. In a self-lubricating pulley, the combination with the pulley made in sections transversely of its axis with a portion of the hub on each section, an oil-chamber within the pulley and on the outer side of the hub, and the adjacent ends of said hub-sections formed with an annular oil-passage between them, a portion of said annular passage extending parallel with the axis of the pulley, of an annular chamber in the inner wall of said portion of the passage parallel with the axis and an annular pervious packing located in said chamber and bridging the passage; substantially as described.

697,722. AUTOMOBILE-FRAME. GEORGE A. HUNT, Reading, Mass., assignor of one-half to F. C. Alden, Reading, Mass. Filed Feb. 11, 1902. Serial No. 64,322. (No model.)

Claim.—1. In an automobile-underframe the combination of a cross-frame for the driving-wheels comprising a substantially vertical yoke, upper and lower outwardly-converging diagonal bars projecting from both sides of said yoke and connected at their outer ends, tubular axle-housings located between the upper and lower diagonal bars on each side, longitudinal members attached to the upper diagonal bars, and diagonal braces connecting said members with the lower diagonal bars and located in substantially the same vertical planes with the members.

2. An automobile-underframe comprising a longitudinal frame structure having side bars formed with a curved portion at their forward ends and having a downwardly-projecting bracket or lug at the extreme front, and a cross-frame for the steering-wheels pivoted to the said bracket or lug underneath the said curved portion.

697,723. CARBONATING-MACHINE. THOMAS E. LEWIS, Jersey City, N. J., and HENRY J. MILLER, Brooklyn, N. Y. Filed Mar. 14, 1901. Renewed Feb. 14, 1902. Serial No. 94,122. (No model.)

Claim.—1. In a carbonating apparatus, the combination with a tank or casing consisting of a lower and an upper portion secured together, of a perforated partition or diaphragm secured between the two portions thereof, a water-pipe provided with an upwardly-extending and having side perforations in communication with the upper portion of the tank or casing above the diaphragm and extending downward on the outside parallel with the lower portion of the casing, a water-pressure supply in communication with the water-pipe at the lower end, a gas-pipe in communication with the water-pipe above the communication with the water-supply, a gas-pipe having side perforations extending into the lower portion of the casing adjacent to the bottom, and a gas-pressure supply in communication with the gas and with the water-pipe, substantially as shown and described.

2. In a carbonating apparatus, the combination with a tank or casing consisting of a lower and an upper portion secured together, of a perforated partition or diaphragm secured between the two portions thereof, a water-pipe provided with an upwardly-extending and having side perforations in communication with the upper portion of the tank or casing above the diaphragm and extending downward on the outside parallel with the lower portion of the casing, a water-pressure supply in communication with the water-pipe at the lower end, a gas-pipe in communication with the water-pipe above the communication with the water-supply, a gas-pipe having side perforations extending into the lower portion of the casing adjacent to the bottom, a gas-pressure supply in communication with the two gas-pipes, and a filling of solid matter in the form of pebbles, &c., in the water-pipe above the communication with the gas-supply pipe therewith, substantially as shown and described.

697,724. TEMPORARY CAP OR COVER HOLDER FOR JARS. AXEL JOHANSEN, San Jose, Cal. Filed Jan. 17, 1901. Serial No. 43,637. (No model.)

Claim.—1. A device of the character described comprising a holder, a ball secured thereto, a ring having intersecting ribs δ , δ' , and means carried by the ball adapted to exert pressure upon said ribs and through the ribs to the ring, substantially as described.

2. A device of the character described comprising a holder, a ball secured thereto, a ring, a rib δ' on said ring and having a cast intermediate of its ends, and a cam carried by the ball adapted to engage said cast to exert pressure upon said rib and through the rib to the ring, substantially as described.

3. A device of the character described comprising a holder, a ball

pivotedly secured thereto, a ring, a rib δ' on said ring, means carried by the ball adapted to engage said rib to exert pressure upon said rib and through the rib to the ring, and a shoulder δ'' on the rib adapted to limit the movement of the ball in one direction, substantially as described.

4. In combination with a receptacle, a cover therefor having an outer depending tapered flange, and means for forcing the cover to its seat comprising a correspondingly tapered ring adapted to overlap the flange of the cover, and a pressure device including a pivoted ball operatively associated with said ring for the purpose set forth.

5. In combination with a receptacle, a cover therefor, and means for forcing the cover to its seat, and comprising a holder, a pressure-exercising device operatively associated with the holder and including a pivoted ball, and an unattached holding-ring adapted to be inserted beneath the pressure device and over the cover, substantially as described.

697,725. VIAL-CARRYING FRAME. JAMES C. JONES, Buffalo, Ky. Filed July 20, 1901. Serial No. 92,145. (No model.)

Claim.—1. In a device of the character described, the combination with two adjustable right-angled bars each provided with vertical notches designed to receive the transverse bars or rods, of slidable bars provided on the inner side of the first-named bars and having L-shaped notches adapted to engage the transverse bars and lock them with relation to the first-named bars.

2. In a device of the character described, the combination with two outer bars provided with notches, of transversely-arranged vial-carrying rods adapted to be seated in said notches and notched inner bars parallel with the first-named bars to engage the transverse rods to lock them in position.

3. In a device of the character described, the combination of two parallel fixed outer bars having vertical notches, two sliding inner bars provided with locking-notches, and connected with the outer bars and working on the latter, a lever eccentrically mounted on an inner bar and engaging the adjacent outer bar.

4. In a device of the character described, the combination of two fixed outer bars adjustably secured together, inner bars secured to the outer bars and adapted to slide with relation thereto; both sets of bars being provided with notches, and the locking-levers secured to adjacent bars for the purpose described.

5. In a device of the character described, the combination of two parallel outer bars, having right-angled slotted ends, whereby they are adjustably secured, and opposite ends providing inwardly-actuating right-angled short arms, each having a notch formed on its extremity, two parallel inner bars, and levers adjustably and locking simultaneously the parallel inner bars.

6. In a device of the character described, the combination of two parallel bars, adapted to be adjustably secured by arms formed at each end, extending forwardly at right angles, inner bars sliding parallel to the outer bars, and actuated by locking-levers, having an engaging lug formed

on their lower pivoted ends and operating in a notch or slot formed in the outer bar.

7. In a device of the character described, the combination of two outer bars, provided with notches, transversely-arranged vial-carrying rods adapted to be seated in said notches, and inner bars having L-shaped notches, said bars slidably secured to the outer bars, and levers pivotedly mounted on the inner bars, and having cut-out portions on their upper ends, and pinning-lugs formed on their lower parts engaging the outer parallel bars, whereby the inner bars are actuated into a locking position.

697,726. MACHINE FOR FLAMING CAR-BODIES. WILLIAM J. KENT, Montpelier, N. H. Filed Mar. 14, 1901. Serial No. 91,527. (No model.)

Claim.—1. In a machine for the purpose stated, the combination with a die provided with an expandible and contractible center block constructed to hold a sheet-metal body which embraces the block, said block filling said body and the side faces of which have contact with, and exert pressure against, all parts of the walls of the body throughout the vertical depth of the block to prevent inward flexure of the body, of a hollow punch adapted to pass over said die and body, and means for forming a flange between said die and punch on the margin of said body.

2. In a machine for the purpose stated, the combination with a die provided with an expandible and contractible center block constructed to hold a sheet-metal body which embraces the same, said block filling said body and the side faces of which have contact with, and exert pressure against, all parts of the walls of the body throughout the vertical depth of the block to prevent inward flexure of the body, an expanding-pin on said punch which engages said block to expand the same outwardly against said body and means for forming a flange between said die and punch on the margin of the body.

3. In a machine for the purpose stated, the combination with a die having a center block embracing a stationary transverse member and a plurality of transversely-pivoted members, of a hollow punch adapted to pass over said block, and means for forming a flange between said die and punch on the margin of a sheet-metal body surrounding said block and located between the block and punch.

4. In a machine for the purpose stated, the combination with a die provided with an expandible and contractible center block constructed to hold a sheet-metal body which embraces the block, said block being of less depth than the width of said body and formed to laterally fill the body from end to end of the block, of a hollow punch adapted to pass over said body and block, and means for holding that portion of the margin of the body which projects beyond the said center block away from the body and compressing the same between the die and punch to form a flange.

5. In a machine for the purpose stated, the combination with a die provided with an expandible and contractible center block adapted to hold a sheet-metal body which embraces the block, and the side faces of which have contact with the walls of the body throughout the vertical depth of the block to prevent inward flexure of the body, of a hollow punch adapted to pass over said die and body, and provided with side parts which

are made of a depth equal to the depth of the block and adapted to surround and fit closely over said body, when the punch is in its inwardmost position, to prevent outward flexure of said body and means for forming a flange between said die and punch on the margin of the body.

6. In a machine for the purpose stated, the combination with a die constructed to hold a sheet-metal body which embraces the die, of a hollow punch adapted to pass over said die and body, said punch embracing a plurality of separable wings constituting, when contracted, a complete closed shell, said wings when free being adapted to swing away from each other to expand the punch.

7. In a machine for the purpose stated, the combination with a die constructed to hold a sheet-metal body which embraces the die, of a hollow punch adapted to pass over said die and body, said punch embracing a plurality of separable wings provided with side parts adapted to pass outside the body to prevent flexure of that part of the body between said side parts of the punch and the die and each provided at its margin with a deflecting-surface.

8. In a machine for the purpose stated, the combination with a die constructed to hold a sheet-metal body which embraces the die, of a hollow punch adapted to pass over said die and body, said punch embracing a plurality of separable wings provided with side parts adapted to pass outside the body to prevent flexure of that part of the body between said side parts and the die, and each wing being provided at both end margins with deflecting-surfaces.

9. In a machine for the purpose stated, the combination with a die constructed to hold a sheet-metal body which embraces the die, of a hollow punch adapted to pass over said die and body, said punch embracing a plurality of separable wings constituting, when contracted, a complete closed shell, said wings, when free, being constructed to swing away from each other to expand the punch, and an inclined deflecting-ring surrounding said die adapted to engage the exterior margins of the hollow punch to close said wings together.

10. In a machine for the purpose stated, the combination with a die provided with a center block constructed to hold a sheet-metal body which embraces the block, said block being made of less depth than that of the body, of a hollow expandible punch adapted to pass over said die and body and provided with interior deflecting-surfaces constructed to engage the margin of said body which projects above the center block to hold said margin inwardly over said block to form a flange thereon, and means associated with the die for contracting the punch upon depression thereof.

11. In a machine for the purpose stated, the combination with a suitable die, constructed to receive and hold a hollow body thereover, of a hollow punch constructed to pass over and outside of said die and body and means for forming a flange on the lower margin of said die and body and said punch after said punch has passed outside of said body.

12. In a machine for the purpose stated, the combination with a die comprising a die-base and a center block, and a punch adapted to pass over said block, of means for holding the center block yieldingly above the die-base, said base being provided below the block with a deflecting-surface.

13. In a machine for the purpose stated, the combination with a die comprising a die-base and a vertically-movable center block thereon constructed to hold a sheet-metal body which embraces the block, of means for holding said block above said base, said block being made of less depth than that of the body, whereby the body projects below the block, a hollow punch adapted to pass over said block and body, and a deflecting-surface on the die-base adapted to turn the lower margin of said body out of the plane of the body to form a flange thereon upon the descent of the punch.

14. In a machine for the purpose stated, the combination with a die comprising a die-base and a center block, of means for yieldingly holding said block above said base, said block being less of width than that of a sheet-metal body embracing the same, whereby said body projects below said block and engages the die-base, and a hollow punch adapted to pass over said block and body, said die-base being provided with a deflecting-surface which turns the lower margin of said body when the center block is depressed upon said base to form a flange thereon.

15. In a machine for the purpose stated, the combination of a die comprising a die-base and a center block, said block being constructed to hold a sheet-metal body which embraces the block, and spring-pressed pins which pass upwardly through said base to hold said block yieldingly out of contact with the base, said block being made of less depth than the body whereby the body projects below said block in contact with the base, of a hollow punch adapted to pass over said block and body and, when depressed, to press the block against said die-base and the die-base being provided with a deflecting-surface which turns the lower margins of the body to form a flange thereon.

16. In a machine for the purpose stated, the combination with a die provided with an expandible and contractible center block constructed

to hold a sheet-metal body which embraces the block, said block filling said body and the side faces of which have pentast with, and exert pressure against, all parts of the walls of the body throughout the vertical depth of the block, to prevent inward flange of the body, of a hollow punch adapted to pass over said block and body, means for forming a flange on the margin of said body between said die and punch and an ejector device for removing said body from the die.

17. In a machine for the purpose stated, the combination with a die provided with a center block constructed to hold a sheet-metal body which embraces the block, of a hollow punch adapted to pass over said block and body, and means for forming a flange on the margin of said body between said die and punch, and an ejector device for removing said body from the die, said ejector device embracing a ring surrounding said die and provided with radial fingers, the inner ends of which are located in contact with the die-face beneath said body when placed on the die.

18. In a machine for the purpose stated, the combination with a die constructed to hold a sheet-metal body which embraces the die, a hollow punch adapted to pass over the die and body, and means for forming a flange on the margin of said body between the die and punch, of a gage-plate for automatically locating the body on the die before the die passes under the punch.

19. In a machine for the purpose stated, the combination with a carrier, a die thereon, a punch which cooperates with said die, the punch being made hollow to pass over the die, and means for forming a flange on the margin of the body between said die and punch, of a gage-plate movable with the punch constructed to locate the body properly on the die before the die passes under the punch.

20. In a machine for the purpose stated, the combination with a carrier, a die on said carrier, and a vertically-reciprocating punch, and means for forming a flange on a body located between the die and punch, of ejector device embracing a ring surrounding the die and adapted to lift the body away from said die and a gage-plate movable with the punch adapted to locate the body properly on the die before it is moved under the punch, said plate being provided with projections adapted to engage the ejector-ring, to seat the same at the same time the body is adjusted on the die.

21. In a machine for the purpose stated, the combination with a die embracing a center block provided with an outwardly-expandible member and constructed to hold a sheet-metal body which embraces the block and formed to laterally fill the body from end to end of the block, a hollow punch adapted to pass over said block and body, and an expanding-pin on said punch adapted to spread the expanding members of the block outwardly against the body, of spring-actuating device tending to hold said expanding members inwardly, and means for forming a flange on the margin of the body between said die and punch.

22. In a machine for the purpose stated, the combination with a die constructed to hold a sheet-metal body which embraces the die, and a hollow punch embracing a plurality of pivoted wings which are adapted to swing away from each other, and which, when closed together, form the shell of the punch, of means engaging the pivoted wings of the punch to hold the same closed during a part of the rising movement of the punch.

23. In a machine for the purpose stated, the combination with a die constructed to hold a sheet-metal body which embraces the die, and a hollow punch adapted to pass over said die and body, said punch embracing a plurality of pivoted wings adapted to swing away from each other, and which, when closed, form the shell of the punch, and means for forming a flange on said body between said punch and die, of spring-actuated pins or studs mounted in said die adapted to engage the free ends of said wings to hold the wings in their closed positions during a part of the rising movement of the punch.

24. In a machine for the purpose stated, the combination of a rotary carrier, a plurality of dies disposed annularly upon the upper surface of said carrier, a reciprocating punch adapted to cooperate severally with said dies, said dies each embracing a center block adapted to hold thereon a sheet-metal body which fits over said block, means for forming a flange on said body between the die and punch, and an ejector device embracing a ring surrounding each of said dies, a vertically-oscillatory lever pivoted between its ends to the machine-frame and provided at one end with fingers or plungers adapted to pass through the openings in the carrier to severally actuate said ejector-rings, and means actuating said lever embracing

25. In a machine for the purpose stated, the combination of a rotary carrier, a plurality of dies disposed annularly upon the upper surface of said carrier, a reciprocating punch adapted to cooperate severally with said dies, said dies each embracing a center block adapted to hold thereon a sheet-metal body which fits over said block, means for forming a flange on the body between the punch and die, and an ejector device embracing a ring surrounding each of said dies, a vertically-oscillatory lever pivoted between its ends to the machine-frame and provided at one end with fingers or plungers adapted to pass through openings in the carrier to severally actuate said ejector-rings, and means actuating said lever embracing

a horizontally-movable slide, and a pivoted dog on said slide adapted to engage an inclined part of said lever.

26. In a machine for the purpose stated, the combination of a rotary carrier, a plurality of dies disposed annularly upon the upper surface of said carrier, a reciprocating punch adapted to cooperate severally with said dies, said dies each embracing a center block adapted to hold thereon a sheet-metal body which fits over said block, means for forming a flange on the margin of said body, and an ejector device embracing a ring surrounding each of said dies, a vertically-oscillatory lever pivoted between its ends to the machine-frame, and provided at one end with fingers or plungers adapted to pass through openings in the carrier to severally actuate said ejector-rings and actuating said lever, and a horizontally-movable knock-off arm adapted to move the body from the die after it has been raised therefrom by the ejector device.

697,727. SWITCH FOR ELECTRIC LAMPS. JAMES F. KEATHE, Philadelphia, Pa., assignor to General Electric Company, a Corporation of New York. Filed Mar. 10, 1906. Serial No. 728,618. (No model.)

Claim.—1. A switch for an incandescent lamp, provided with a holder for the lamp-base, a casing for the switch mechanism, a key having its operating-arm in a line axial to the holder, a fixed contact yieldingly mounted in a vertical plane, a movable contact rotated by the key-stem in cooperative relation to the fixed contact, and means for effecting a snapping rupture of the circuit when the contacts separate.

2. A socket for incandescent electric lamps, provided with a receptacle for the lamp-base, a casing connected to the bottom thereof and separable therefrom, switch mechanism housed within the casing, a lateral pipe connection in the casing through which the current leads may be led, and a key below the casing turning on a plane transverse to the axis of the lamp and socket.

3. A socket for incandescent electric lamps, provided with a receptacle for the lamp-base, a casing below the same, snap-switch mechanism within the casing, said casing being formed of separable parts to admit access to its interior, a lateral pipe connection from the casing for connection with a tubular bracket to house the current leads, and a key controlling the switch turning on a plane transverse to the axis of the lamp-socket.

4. A socket for incandescent electric lamps, provided with a receptacle for the lamp-base mounted on an insulating-support, means therefor for affixing connection with the lamp-terminals, a casing mechanically connected with the socket, provided with a lateral tubular connection for the circuit leads, a switch in said casing composed of an electrically-mounted terminal, a rotatable contact cooperating therewith, a key on the bottom of the casing mounted to turn in a plane transverse to the axis of the lamp and socket, a hot-motion connection being provided between the key and the rotatable contact, and a spring and cam controlling the movement of the contact to effect a snapping motion on opening the circuit.

697,728. MACHINE FOR TRIMMING CORNER-PINCHES. FRED LAYMAN, Syracuse, N. Y. Filed Oct. 4, 1901. Serial No. 77,617. (No model.)

Claim.—1. Is a machine of the described class, a plunger with a rigid head having an angular cutting edge and provided with a longitudinal recess terminating at the cutting end of said plunger, a spring-actuated triangular-shaped leader projecting from said recess and terminating at its free end in an angular apex, said apex normally removed some distance from the end of said plunger, and a plate in the line of movement with said plunger provided with an opening therethrough con-

responding in form to the head of said plunger and having an angular cutting edge around the entire mouth of said opening through said plate.

2. Is a machine of the described class a plunger with longitudinal opening extending into the shank thereof, a movable spring-actuated leader riding in said longitudinal opening and terminating in a triangular apex with straight lines from the point of said apex to the outer edges of said leader, a head having a right-angle cutting edge on said plunger, a plate in proximity to said plunger having an opening conforming to the head thereof, and guide-plates with suitable beveled channels adapted to hold therein the angular sides of the material to be operated upon.

3. Is a machine of the described class, a plunger with a rigid removable head having an angular cutting edge and having a longitudinal opening therein, a spring-actuated triangular-shaped leader projecting normally to some distance beyond said removable head and terminating in an apex, a plate-holder with central orifice therein in line with said removable head, and a detachable plate secured to said plate-holder with central opening coincident with that of the opening in the plate-holder and also in line with said head.

4. Is a machine of the described class, a cutting-plunger with spring-actuated triangular leader normally removed from the cutting-face of said plunger, a plate-holder with central orifice and rigidly connected with a parallel head and slightly removed therefrom, posts connecting said head, a cutting-plate removably connected with said plate-holder and provided with a central opening corresponding to the contour of the cutting edge of said leader.

697,729. TOILET-POWDER BOX. ELIA H. LINTHURN, New York, N. Y. Filed Oct. 28, 1901. Serial No. 78,957. (No model.)

Claim.—1. In an article of the class described, the combination with a box, of a thin and flexible diaphragm loosely fitting the interior of the box, and provided with a plurality of centrally-grouped apertures, whereby the diaphragm is adapted for being flexed to eject the comminuted contents through the centrally-grouped apertures, substantially as described.

2. The combination in an article of the class described, of a box comprising a circular body, a cover therefor, and a circular diaphragm loosely fitting the interior of the box, and adapted to be moved to the bottom thereof, said diaphragm being made of thin flexible material, and provided with a plurality of apertures centrally grouped with reference to the periphery thereof, whereby the diaphragm is adapted for being flexed to eject the comminuted contents through the centrally-grouped apertures, substantially as described.

3. In an article of the class described, the combination with a box, of a thin, flat and flexible diaphragm loosely fitting the interior of the box, and provided with a plurality of apertures grouped at the central and flat portion thereof, whereby the diaphragm is adapted for being flexed to eject the comminuted contents through the centrally-grouped apertures, substantially as described.

697,730. ISOMERIZATION DERIVATIVE AND PROCESS OF MAKING SAME. ARTHUR LAMMERS, Frankfurt-on-the-Main, Germany, assignor to Farbwerke, vorm. Meister, Loeb & Co., Höchst-on-the-Main, Germany, a Corporation of Germany. Filed July 17, 1901. Serial No. 61,622. (Specimen.)

Claim.—1. Process for the manufacture of dialkylated acids of isovaleric and bromoisovaleric acids, which consists in treating the compound of isovaleric acid described with dialkylated oxides, substantially as set forth.

2. As a new product, the dialkylated acid of isovaleric acid, distilling between 205° and 205° at twenty millimeter pressure, soluble with difficulty in water, readily soluble in alcohol, and benzenes, but less soluble in ether, substantially as set forth.

697,781. PROCESS OF MAKING LITHOPHON. BEN F. LEHR, Cleveland, Ohio, assignor to the Grinnell Chemical Company, Cleveland, Ohio, a Corporation of Ohio. Filed Nov. 21, 1906. Serial No. 57,590. (No specimen.)

Claim.—1. The process for preparing from solution, lithopone of

various grades and a soluble commercial by-product probably of sodium, which consists in preparing separate solutions of zinc sulfide and barium sulfide, which solutions are mixed with each other and with that of a third salt adapted to enter into combination with a fixed acid group from the first-named salts, the same being brought together in equivalent and calculated amounts to produce and precipitate lithopone of the desired percentage, and leave in solution the soluble by-product, substantially as described.

2. The herein-described process for manufacturing lithopone of various grades and a by-product of sodium hydrosulfide, which consists in preparing separate solutions of zinc sulfide and barium sulfide, which solutions are mixed with each other and with that of sodium bisulfide, all in equivalent and calculated amounts to produce and precipitate the desired grade of lithopone and leave the sodium hydrosulfide in solution, substantially as described.

697,782. DRAFT-EQUALIZER. GEORGE LEHMAN, Detroit, Mo. Filed Nov. 23, 1901. Serial No. 52,614. (No model.)

Claim.—In a draft-equalizer, the combination with the pole carrying the loose-mouth-yoke at its forward end, the cross-piece pivoted near the inner end of the pole to provide a long and short arm, the singletons mounted on the long arm, the connection leading from the short arm, the hinged guide for said connection carrying a roller-bearing, a cross-bar connected centrally to said connection, and a pair of singletons carried by said cross-bar.

697,788. MULTIPLE-CONDUCTOR SYSTEM. ALEXANDER D. LEWIS, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Sept. 27, 1901. Serial No. 78,708. (No model.)

Claim.—1. The combination of a source of direct current, an inverted rotary converter fed thereby, a second rotary converter connected so as to receive alternating current from the inverted rotary converter, and a multiple-conductor direct-current system including conductors extending from the direct-current ends of both of said converters.

2. The combination of a source of direct current, an inverted rotary

converter fed thereby, means for altering the electromotive force of alternating current derived from said inverted rotary converter, a rotary converter fed by each alternating current, and a plurality of coöperating conductors extending from the direct-current ends of both converters.

3. The combination of two rotary converters, connections between the alternating-current leads of both rotary converters, and means for changing the electromotive force of the alternating current supplied by one rotary converter to the other.

4. The combination of a plurality of rotary converters, connections between the alternating-current terminals of both rotary converters, means for deriving a point having a potential neutral with respect to the windings of both converters, a neutral conductor extending from said neutral point, and other conductors extending from the direct-current terminals of said rotary converters and constituting with said neutral conductor a common distribution system.

5. The combination of a source of direct current, means for deriving therefrom a variable alternating electromotive force, means for converting said variable alternating electromotive force into a variable direct electromotive force, and means for impressing said variable direct electromotive force upon a consumption-circuit.

6. The combination of a main source of direct current, mains extending therefrom, and means for subdividing the difference of potential between said mains, said means consisting of two rotary converters, one of which is driven by the other through the medium of alternating currents of regulable electromotive force, the direct-current terminals of one of said rotary converters being connected to said mains and the direct-current terminals of the other rotary converter to a separate set of mains.

897,784, SAFETY DEVICE FOR CIRCUIT-CLOSERS. **FREDERICK MACKINTOSH**, Schenectady, N. Y., assigner to General Electric Company, a Corporation of New York. Filed Aug. 28, 1901. Serial No. 72,940. (No model.)

Claim.—1. The combination with a line-switch and a starting-rheostat, of a spring-actuated locking device for said switch, and means operatively connected with the movable arm of said rheostat for putting a tension on said spring.

2. The combination with a line-switch and a starting-rheostat, of a locking device for said switch comprising a pivoted dog adapted to move into the path of said switch, and means operatively connected with the arm of said rheostat for returning said dog to an inoperative position.

3. The combination with a line-switch and a starting-rheostat, of a locking device for said switch comprising a pivoted spring-actuated dog adapted to move into the path of said switch, and a rod operatively connected with the arm of said rheostat for putting a tension on said spring, and returning said dog to an inoperative position.

4. The combination with a line-switch and a starting-rheostat, of a locking device for said switch, comprising a pivoted dog adjacent to said switch, a lever engaging with said dog, and a rod pivoted to the lever and connected with the rheostat-arm.

5. The combination with a line-switch and a starting-rheostat, of a locking device for said switch, comprising a pivoted dog to enter into the path of said switch, means for exerting a forward pressure on said dog, a lever on which said dog rests, a rod connected with the lever and with the rheostat-arm, and a spring to return the lever to a normal position.

6. The combination with a line-switch and a starting-rheostat, of a locking device for said switch, comprising a pivoted dog to enter into the path of said switch, means for causing said dog to press against the switch-blade when closed, a lever on which the dog rests, a rod pivoted to the lever and having a longitudinal slot, and a pin on the rheostat-arm engaging with said slot.

897,785. GASTER. GEORGE S. MASON, Babylon, N. Y., assignor to the Acme Ball Bearing Gaster Company, a Corporation of New York. Filed Aug. 31, 1909. Serial No. 28,674. (No model.)

Claim.— 1. The combination with a center-body and a bearing-ball mounted therein so as to be free to rotate in all directions, of a bearing-ring surrounding said center-body, said ring being adapted to form a track for said bearing-ball to roll upon, substantially as described.

2. The combination of a caster-body and a bearing-ball mounted therein so as to be free to rotate in all directions, of a bearing-ring surrounding said caster-body, said ring having an annular concave inner surface adapted to form a track for said bearing-ball to roll upon, substantially as described.

2. The combination with a center-body and a bearing-ball mounted therein so as to be free to rotate in all directions, of a bearing-ring surrounding said center-body, said ring having a substantially cylindrical outer surface and an annular concave inner surface adapted to form a track for said bearing-ball to roll upon, substantially as described.

4. The combination with a center-body, a bearing-ball mounted therein, and a universal anti-friction-bearing for said bearing-ball, of a bearing-ring surrounding said center-body, said ring being adapted to form a track for said bearing-ball to roll upon, substantially as described.

5. The combination with a center-body and a bearing-ball mounted therein so as to be free to rotate in all directions, of a socket for said center-body having a pinile concentrically arranged with reference to the vertical axis of the socket, an annular bearing-surface concentric with the pinile, a socket-piece within which said pinile is free to rotate, said socket-piece having an annular bearing-surface, antifriction-balls located between said annular bearing-surfaces, and a bearing-ring surrounding said center-body, said ring being adapted to form a track for said bearing-ball to roll upon, substantially as described.

6. The combination with a center-body and a bearing-ball mounted therein so as to be free to rotate in all directions, of a socket for said center-body having a pinhole arranged to one side of but parallel with the vertical axis of the center, and a bearing-ring surrounding said center-body, said ring being adapted to form a track for said bearing-ball to roll upon, substantially as described.

7. The combination with a center-body and a bearing-ball mounted therein as so to be free to rotate in all directions, of a socket for said center-body having a pinion arranged to one side of but parallel with the vertical axis of the center, and a bearing-ring surrounding said center-body, said ring having an annular concave inner surface adapted to form a track for said bearing-ball to roll upon, substantially as described.

8. The combination with a waster-body, a bearing-ball mounted thereon, and a universal anti-friction-bearing for said bearing-ball, of a socket for said waster-body having a pinole arranged to one side of but parallel with the vertical axis of the waster, and a bearing-ring surrounding said waster-body, said ring being adapted to form a track for said bearing-ball to roll upon, substantially as described.

9. The combination with a center-body, a bearing-ball mounted therein, and a universal anti-friction-bearing for said bearing-ball, of a socket for said center-body having a pinion arranged to one side of but parallel with the vertical axis of the center, and a bearing-ring surrounding said center-body, said ring having a substantially cylindrical outer surface and an annular concave inner surface adapted to form a track for said bearing-ball to roll upon, substantially as described.

897,786. FIRE-ESCAPE JOHN T. MAHAR, New York, N. Y.
Filed Nov. 26, 1901. Serial No. 52,575. (No model.)

Claim.—1. In a fire-scope, a circular block the perimenter of which is provided with a spiral groove, a yoke-shaped suspending device be-

tween the opposite sides of which the said block is mounted and free to turn through a part of a revolution, said block being also provided with side lugs or projections which operate in connection with the yoke-shaped suspending device to limit the turning movement thereof and in connection with which the yoke-shaped suspending device operates, substantially as shown and described.

2. In a fire-escape, a circular block the perimeter of which is provided with a spiral groove, a yoke-shaped suspending device between the opposite sides of which the said block is mounted, and free to turn through a part of a revolution, said block being also provided at the opposite sides thereof with lugs or projections in connection with which the yoke-shaped suspending device operates to limit the movement of the block, and a rope or cord wound around said block and means for holding said rope or cord in said groove, substantially as shown and described.

3. In a fire-escape, a circular block, the perimeter of which is provided with a spiral groove, and a yoke-shaped suspending device, between the opposite sides of which the said block is mounted, and free to turn through a part of a revolution, said block being also provided at the opposite sides thereof with lugs or projections in connection with which the yoke-shaped suspending device operates, and a rope or cord wound around said block and means for holding said rope or cord in said groove, consisting of a plate mounted to one side of said block diametrically thereof, and angular members hinged to the opposite ends and extending across the perimeter of said block and radially inwardly, and the inner ends of which are dotted and adapted to receive a shaft or bolt which passes centrally through said block, substantially as shown and described.

4. In a fire-escape, a circular block, the perimeter of which is provided with a spiral groove, and a yoke-shaped attachment, between the sides of which the block is mounted, said block being provided with a central shaft, the ends of which pass through slots formed in the ends of the sides of the yoke-shaped attachment, one side of said yoke-shaped attachment being also provided with a hinged member, substantially as shown and described.

5. In a fire-escape, a circular block, the perimeter of which is provided with a spiral groove, and a yoke-shaped attachment, between the sides of which the block is mounted, said block being provided with a central shaft, the ends of which pass through slots formed in the ends of the sides of the yoke-shaped attachment, one side of said yoke-shaped attachment being also provided with a hinged member, and said block being also provided with means for holding the rope thereon consisting of a plate secured diametrically of one side thereof and provided at its ends with hinged members extending across the perimeter thereof, and inwardly radially of the other side thereof and the inner ends of which are dotted, substantially as shown and described.

6. In a fire-escape, a circular block, the perimeter of which is provided with a spiral groove and a yoke-shaped attachment between the sides of which the block is mounted, one side of said attachment being

provided with a hinged member, and the ends of both sides being provided with oblong slots or openings and said block being provided with a stationary shaft, the ends of which pass through said slots or openings, substantially as shown and described.

7. In a fire-escape, a circular block, the perimeter of which is provided with a spiral groove and a yoke-shaped attachment between the sides of which the block is mounted, one side of said attachment being provided with a hinged member, and the ends of both sides being provided with oblong slots or openings and said block being provided with a stationary shaft, the ends of which pass through said slots or openings, said block being also provided with hinged devices for holding a rope thereon and the ends of which are held in position by one side of the yoke-shaped attachment, substantially as shown and described.

8. A fire-escape comprising a circular block, the perimeter of which is provided with a spiral groove, a yoke-shaped suspending device between the opposite sides of which the said block is mounted and free to turn through a part of a revolution, said block being also provided with side lugs or projections which operate in connection with the yoke-shaped suspending device to limit the movement of said block and in connection with which the yoke-shaped suspending device operates, a roller mounted between the sides of the yoke-shaped device adjacent to said block and a rope which is passed around said block, and one end of which is passed through the yoke-shaped suspending device over said roller, substantially as shown and described.

697,787. ARCH FOR BOILER-FURNACE. JOHN F. HENNING. Chicago, Ill. Filed Dec. 9, 1901. Serial No. 86,188. (No model.)

Claim.—In a boiler-furnace, the combination with the grate, the boiler-front and the boiler, of an arch spanning said grate and divided transversely between its ends into two independent parts, one of which may be removed and replaced without removing the other part, a parallel or concentric arch above each part of said first-named arch and independent of the latter, each last-named arches extending to the lower ends of the boiler-front and the forward end of the boiler to protect same from direct heat and prevent smoke and gases from entering the space between said front and the forward end of the boiler.

697,788. PHOTOGRAPHIC INSTRUMENT. HERMAN E. MILLER. Milwaukee, Wis. Filed May 4, 1901. Serial No. 86,768. (No model.)

Claim.—1. In a device of the described class, the combination of an enclosing case, provided with a light-aperture, adapted to substantially enclose the parallel rays from the interior; a specimen located within the case, and diagonally disposed across the horizontal plane of the light-aperture; and means for supporting a concoidal plate within the case in substantially the focal plane of the specimen, but at an angle to the specimen, whereby the rays reflected from the specimen are distorted on the plate.

2. In a device of the described class, the combination of an enclosing case provided with a light-aperture; a specimen located in said case in a position to receive the rays of light coming through said aperture; and means for supporting a concoidal plate approximately in the focal

plane of the specimen, but at an angle thereto, said light-aperture being of such relatively small dimensions as to exclude substantially all the parallel rays from the specimen.

3. In a device of the described class, the combination of a rotary casing, having a recess in one side, and having a light-admitting aperture formed to exclude parallel rays, located in the recess, on the axial line of rotation; a specimen mounted in the casing and adapted to receive the light from said aperture; and means for supporting a stationary annular plate within the casing in such a position, and of such dimensions, as to substantially coincide with the focal plane of the specimen and receive the light-rays therefrom at all points of casing adjustment.

4. In a device of the described class, the combination of a rotary casing; a specimen located therein at one side of the axis of rotation; said casing having a light-admitting aperture located on the axis of casing rotation, and formed to substantially exclude parallel rays; and means for supporting a stationary annular plate within the casing, substantially in one or more focal planes of the specimen, when the casing is at different points of adjustment.

5. In a device of the described class, the combination of a rotary casing provided with a recess having vertical opaque walls, and having a light-admitting aperture located on the axis of casing rotation; a specimen located within the casing at one side of the axis of rotation, and arranged to receive rays of light from the aperture; and means for supporting a stationary annular plate within the casing, in substantially the focal plane of the specimen at one or more points of casing adjustment.

6. In a device of the described class, the combination of an inclining casing provided with one or more light-admitting apertures, formed to exclude parallel rays from the interior; a specimen adapted to receive light from each such aperture; and means for supporting a stationary plate, substantially in the focal plane of the specimen.

697,789. COMPOUND FAUCET FOR FLUIDS. CERNIVAL & LOTURINI Y MURRIETA, Madrid, Spain. Filed July 30, 1901. Serial No. 60,134. (No model.)

Claim.—1. A compound cock or faucet comprising a casing having an outlet, and two inlets with a space between them situated opposite to the outlet, and a plug having in it a transverse part wider at one end than the other, the lower end of said part being of greater width than the space between the inlets and of less width than said space plus the width of one of said inlets.

2. A compound cock or faucet comprising a casing with two inlets and a common outlet, and a rotatable plug having a part which is wider at one end than at the other, the wider end of said part being substantially equal in width to one inlet plus the space between the inlets, and its narrower end substantially equal in width to one inlet.

697,740. BEEHIVE-STEEL PLANT. CHARLES E. MCCLURE, JR., and LEONARD C. R. HOLMES, Chicago, Ill. Filed Jan. 7, 1901. Serial No. 42,268. (No model.)

Claim.—1. The combination of a plurality of converter vessels, arranged in groups, receiving-crane each operative with a group of the converter vessels, and casting-crane, one for each receiving-crane and co-operative therewith and having their pivotal masts or posts at different fixed distances from the pivotal posts of the receiving-crane with which they co-operate for the pouring-crane to pour at different points in relation to the converter vessels, substantially as described.

2. The combination of a group of converters comprising three vessels, two receiving-crane jointly serving the three vessels, and two casting-crane, one for each receiving-crane, one casting-crane having its pivotal mast or post at a greater distance than the other from the pivotal post of the receiving-crane operating therewith for the two casting-crane to pour at different points in relation to the converter vessels, substantially as described.

3. The combination of a group of converters comprising three vessels, two receiving-crane jointly serving the three vessels, two casting-

crane, one for each receiving-crane, one casting-crane having its pivotal mast or post at a greater distance than the other from the pivotal post of the receiving-crane operating therewith, and two independent pouring-trucks, one for each casting-crane, each truck operative only in connection with its particular casting-crane, substantially as described.

4. The combination of a group of converters comprising three vessels, two receiving-crane jointly serving the three vessels, each crane having its own ladle, two casting-crane, one for each receiving-crane, each casting-crane having its own ladle and one casting-crane having its pivotal mast or post at a greater distance than the other from the pivotal post of the receiving-crane operating therewith for each set of cranes to be independently operative of the other set and both sets conjointly operating in serving the division of converters, substantially as described.

5. The combination of two receiving-crane, two casting-crane, one for each receiving-crane, one casting-crane having its pivotal mast or post at a greater distance than the other from the pivotal post of the receiving-crane operating therewith, and two independent pouring-trucks, one for each casting-crane for conducting the pouring operation at different distances from the converter vessels, substantially as described.

6. The combination of a group of converters comprising three vessels, two receiving-crane jointly serving the three vessels, two casting-crane, one for each receiving-crane, one casting-crane having a greater radius of action than the other and having its pivotal mast or post at a greater distance than the other from the pivotal post of the receiving-crane operating therewith, a separate and independent pouring-truck for each casting-crane, and one with casting or ingot molds thereon operatively movable on the two independent pouring-trucks, substantially as described.

697,741. BEEHIVE. GYÖRGY WERNER, Lager, Austria-Hungary. Filed Nov. 18, 1901. Serial No. 52,267. (No model.)

Claim.—A beehive, consisting of a casing, horizontal and vertical partitions therein dividing the same into longitudinal compartments, detachable rear walls for said casing, a removable glass partition in the rear part of each compartment, flaps for supporting the same, a bee-passage through one of said flaps in each compartment, bee-passages, one for each compartment, in the front wall of the casing, bee-passages in the horizontal partition of the casing adjacent the front wall, a valve in each upper compartment, pivoted to and supported upon said partition, and controlling one of said last-mentioned bee-passages, each frame in said compartments, provided each with downwardly-projecting pins, the pins of the front frame of each upper compartment being located in the path of the valve of said compartment for limiting the movement of the same, substantially as set forth.

697,742. HAY-FORK. BETH A. REMOND, Fowlerville, Mich. Filed Sept. 20, 1901. Serial No. 77,048. (No model.)

Claim.—1. In a hay-fork, the combination of pivoted grapple-teeth provided with projections extending above the pivot, a link pivoted to each of said projections, an intermediate link pivoted between the first-mentioned links, a guide and stop arranged to allow the linkage to pass a straight line cutting the joints of the linkage to the grapple-teeth, and means for stopping the linkage immediately above the straight line.

2. In a hay-fork, the combination of pivoted grapple-teeth provided with projections extending above the pivot, a link pivoted to each of said projections, an intermediate link pivoted between the first-mentioned links, a guide adapted to constrain the movement of said intermediate link, and to allow it to turn to a small, and prevent it turning to a large extent, and a stop arranged to allow the linkage to pass a straight line cutting the joints of the linkage to the grapple-teeth, and means for stopping the linkage immediately above the straight line.

3. In a hay-fork, the combination of two parallel strips shaped in the form of a frame having two uprights and a cross-bar, the two strips being spaced from each other at the top, a bar extending between the ends of said uprights, the ends of said bar being secured between said strips to space them from each other at their ends, then pivoted to said frame and having extensions, links pivoted to said extensions, connected with each other and guided by a part extending between said strips where they form said uprights.

4. In a hay-fork, the combination of two parallel strips shaped in the form of a frame having two uprights and a cross-bar, the ends of said uprights being bent outwardly from said uprights, the two strips being spaced from each other at the top, a bar extending between the ends of said uprights, the ends of said bar being secured between said strips to space them from each other at their ends, then pivoted between the laterally-extending portions of said strips and having extensions, links pivoted to said extensions, connected with each other and guided by a part extending between said strips where they form said uprights.

5. In a hay-fork, the combination of two parallel strips shaped in the form of a frame having two uprights and a cross-bar, the two strips being spaced from each other at the top, a bar consisting of two pieces lying parallel and side by side extending between the ends of said uprights, the ends of said bar being secured between said strips to space them from each other at their ends, the constituent pieces of said bar being bent outward to form an eye, then pivoted to said frame and having extensions, links pivoted to said extensions, connected together and guided by a part extending between said strips where they form said uprights, and a trip-rope secured to said links and extending through said eyes.

6. In a hay-fork, the combination of two parallel strips shaped in the form of a frame having two uprights and a cross-bar, said strips being spaced from each other at the top and bottom, then pivoted on opposite sides of said frame and having upward extensions, links pivoted to said extensions and a link extending between said strips where they form the uprights and pivoted to the first-mentioned links, the intermediate link being provided with stops adapted to prevent its turning too far from a horizontal position by contacting the frame.

7. In a hay-fork, the combination of two parallel strips shaped in the form of a frame having two uprights and a cross-bar, said strips being spaced from each other at the top and bottom, then pivoted on opposite sides of said frame and having upward extensions, parallel bars pivoted upon opposite sides of each of said extensions, and a link extending between said strips where they form the uprights and having in each pivoted between said parallel bars.

697,743. DEVICE FOR DRYING HAIR. WILLIAM J. O'HARA, Bridgeport, Conn., assignor of one-third to Charles F. Tucker, Hartford, Conn. Filed Feb. 28, 1900. Renewed Feb. 28, 1903. Serial No. 64,194. (No model.)

Claim.—1. A hair-drying device comprising a hollow head, a heat conducting and diffusing body, a non-conductive handle therefor, and an independent toothed strip secured to said body, said strip having a series of relatively thin teeth which are wide at their bases and taper abruptly at their points, whereby a large drying area is provided.

2. A hair-drying device comprising a hollow, chamber body portion of heat conducting and diffusing material, said body portion having a water-inlet in one end thereof, means for closing said water-inlet, a non-conductive handle for said body, and an independent toothed strip secured to said body but removable therefrom, said strip being provided with relatively thin teeth which are wide at their bases and taper abruptly toward their points, whereby a large drying area is provided.

3. A hair-drying comb or device having a hollow, chamber body portion of heat conducting and diffusing material to form a receptacle for the heating medium, a water-inlet in one end of said body, a non-conductive handle adapted to screw into and close said water-inlet and thereby serve as a handle and stopper for the said body portion, and an independent toothed strip secured to but removable from said body portion, said strip being provided with relatively thin hollow teeth which are wide at their bases and taper abruptly toward their points whereby a large drying area is provided.

697,744. AIR FILTER AND RECEPTACLE. JOHN M. GANN, Chicago, Ill., assignor of one-third to Carl G. Kjerfve, Chicago, Ill. Filed Aug. 12, 1901. Serial No. 73,664. (No model.)

Claim.—1. In an air filter and receptacle, the combination of an oscillating filter, a journal or pivot-pin on each end of the filter, a frame or band having a slit in one side into which one of the pivot-pins is removably mounted, hinged journal-bases on the inner wall of the frame or band removably mounting both journals or pivot-pins of the filter, a receptacle adapted to receive the frame or band and have the same removably and rigidly entered into its top, a cover for the receptacle over the filter slidable over and around the frame or band to rest against the top rim of the receptacle, and a handle for oscillating the filter, substantially as described.

2. In an air filter and receptacle, the combination of a cylindrical oscillating filter having conical ends, a rounded cover-carrier between the ends and a hinged lid or cover, a journal or pivot-pin on each end of the filter, a frame or band in which the filter is removably mounted, hinged journal-bases on the inner wall of the frame or band removably mounting the journals or pivot-pins of the filter, a handle or arm on one of the journals or pivot-pins, and a receptacle adapted to receive the frame or band and have the same removably entered into its top, substantially as described.

697,745. LOOM. JONATHAN B. FAIRBANKS, Minneapolis, Minn. Filed Nov. 25, 1901. Serial No. 52,659. (No model.)

Claim.—1. In a loom, a clip provided upon each side of the warp-threads and adjustable lengthwise thereof and over which the weft-threads are passed.

2. In a loom, a clip provided upon each side of the warp-threads and adjustable lengthwise thereof and over which the weft-threads are passed, one of said devices at least being adjustable toward the other.

3. In a loom, a clip adjustable lengthwise of the warp-threads and having a finger substantially parallel with said threads and over which the warp-threads are passed.

4. In a loom, clips provided upon each side of the warp-threads and adjustable lengthwise thereof and having fingers substantially parallel with said threads and around which the warp-threads are passed.

5. A loom, comprising end pieces between which the warp-threads are stretched and side bars running parallel with said threads, and clips adjustably arranged on said bars and having fingers around which the warp-threads are passed and dropped as the ends are moved.

6. A hand-loom, comprising end pieces between which the warp-threads are stretched, parallel bars connecting said end pieces, clips adjustably arranged on said bars and having fingers around which the warp-threads are passed and one of said bars being laterally adjustable.

7. A hand-loom, comprising end pieces between which the warp-threads are stretched, side bars connecting said end pieces, means provided on said bars to engage and hold the warp threads or threads and one of said bars being laterally adjustable to adapt the frame for work of different width.

8. A hand-loom, comprising end pieces between which the warp-threads are stretched, fixed bars connecting said end pieces, a bar slidable in grooves in said end pieces toward or from either of said fixed bars, means for securing said slidable bar and warp-thread-engaging device provided on one of said fixed bars and said slidable bar.

9. A hand-loom, comprising end pieces between which the warp-threads are stretched, fixed bars connecting said end pieces, a movable bar arranged between said fixed bars, means for securing said movable bar, and clips provided on said movable bar and one of said fixed bars and adjustable lengthwise thereof and provided with fingers extending substantially parallel with the warp-threads and around which the warp-threads are passed.

897,746. RASH-BAR FOR GREENHOUSES OR OTHER GLAZED STRUCTURES. PAUL H. PHINNEY, Saratoga, N. Y. Filed June 28, 1891. Serial No. 66,342. (No model.)

Claim.—1. A rash-bar for greenhouses and other glazed structures, comprising a metal bar of substantially U shape, a wooden bar the larger part of which is received within the channel of the metal bar, a portion of the wooden bar extending between the glasses and projecting beyond the same and receiving the device securing the glasses, there being shoulders at either side of the projecting portion of the wooden bar upon which the glasses rest and are supported and fastening devices for connecting the metal and wooden bars, substantially as set forth.

2. A rash-bar for greenhouses and other glazed structures, comprising a wooden bar having a portion of reduced width forming a rib with

a shoulder at either side, a metal bar receiving the main portion of the wooden bar, and the rib portion of the wooden bar being between the glasses and projecting beyond the same, and fastening devices passing through the metal bar from the under side into the wooden bar for connecting the parts, substantially as set forth.

3. A rash-bar for greenhouses and other glazed structures, comprising a wooden bar having a portion of reduced width forming a rib with a shoulder at either side, a metal bar receiving the main portion of the wooden bar and the rib portion of the wooden bar being between the glasses and projecting beyond the same and fastening devices passing through the metal bar into the wooden bar for connecting the parts, and moisture-trenches connected to and supported by and coming at opposite longitudinal sides of the metal bar, substantially as set forth.

4. A rash-bar for greenhouses, comprising a wooden bar having a rising projecting longitudinal rib, a U-shaped metal bar surrounding the larger portion of the wooden bar and adapted at its free edges to come up to the under surface of the glass and completely inclose the part of the wooden bar beneath the glass, the rib of the wooden bar coming between the glasses and projecting above the same, there being grooves upon the opposite sides of the projecting rib to receive putty into which the glasses are set, and fastening devices passing through openings in the lower portion of the U-shaped metal bar into the wooden bar for connecting the parts, substantially as set forth.

5. A rash-bar for greenhouses comprising a wooden bar having a rising projecting longitudinal rib, a U-shaped metal bar surrounding the larger portion of the wooden bar and adapted at its free edges to come up to the under surface of the glass and completely inclose the part of the wooden bar beneath the glass, the rib of the wooden bar coming between the glasses and projecting above the same, there being grooves upon the opposite sides of the projecting rib to receive putty into which the glasses are set, and screws passing through openings in the lower portion of the U-shaped metal bar into the wooden bar for connecting the parts, and a moisture-trench below the U-shaped metal bar with upturned edges and located parallel with the metal bar and held thereby by the same screws that connect the metal and the wooden bars, substantially as set forth.

6. A rash-bar for greenhouses comprising a wooden bar having a rising projecting longitudinal rib, a U-shaped metal bar surrounding the larger portion of the wooden bar and adapted at its free edges to come up to the under surface of the glass and completely inclose the part of the wooden bar beneath the glass, the rib of the wooden bar coming between the glasses and projecting above the same, there being grooves upon the opposite sides of the projecting rib to receive putty into which the glasses are set, screws passing through openings in the lower portion of the U-shaped metal bar into the wooden bar for connecting the parts, a moisture-trench below the U-shaped metal bar with upturned edges and located parallel with the metal bar and held thereby by the same screws that connect the metal and the wooden bars, the openings in the metal bar being of larger area than the screws passing therethrough, and the openings for the screws in the moisture-trench being provided with a neck for deflecting the moisture from the screws, and the said neck being received in the openings in the metal bar, substantially as set forth.

7. A rash-bar for greenhouses and other glazed structures, comprising a wooden bar, a metal bar receiving a part of the wooden bar, and a part of the wooden bar being between the glasses, and projecting beyond the same, and fastening devices for connecting the metal and wooden bars, there being openings through the lower portion of the metal bar and the wooden bar not entirely filling the metal bar, so that an appreciable internal chamber is formed between the same and the base of the metal bar to receive any collected moisture passing between the said bars, substantially as set forth.

8. A rash-bar for greenhouses and other glazed structures, comprising a wooden bar having a portion of reduced width forming a rib with a shoulder at either side, a metal bar receiving the main portion of the wooden bar and the rib portion of the wooden bar being between the glasses and projecting beyond the same and fastening devices passing through the metal bar into the wooden bar for connecting the parts, moisture-trenches connected to the said parts for receiving the condensation from the under side of the glasses and water that may leak through the structure and a plate of metal over and longitudinal with the projecting portion of the wooden bar and secured thereto with the edges of the plate extending down to and preferably bearing upon the outer surfaces of the glasses, substantially as set forth.

9. A rash-bar for greenhouses and other glazed structures, comprising a wooden bar having a portion of reduced width forming a rib with a shoulder at either side, a metal bar receiving the main portion of the wooden bar and the rib portion of the wooden bar being between the glasses and projecting beyond the same, fastening devices passing through the metal bar into the wooden bar for connecting the parts, and a plate of metal over and longitudinal with the projecting portion of the wooden bar and secured thereto with the edges of the plate extending down to and

and preferably bearing upon the outer surface of the glasses, substantially as set forth.

10. A rash-bar for greenhouses, comprising a wooden bar having a rising projecting longitudinal rib, a metal bar surrounding the larger portion of the wooden bar and adapted at its free edges to come up to the under surface of the glass and completely inclose the part of the wooden bar beneath the glass, the rib of the wooden bar coming between the glasses and projecting above the same, and moisture-trenches connected to the said parts for receiving the condensation from the under side of the glasses and water that may leak through the structure, substantially as set forth.

897,747. RASH-BAR FOR GREENHOUSES. PAUL H. PHINNEY, Saratoga, N. Y. Filed July 28, 1891. Serial No. 66,343. (No model.)

Claim.—1. A rash-bar for greenhouses and other glazed structures, comprising a main supporting-bar of substantially U shape in cross-section, auxiliary bars of heavy bent sheet metal resting upon and carried by the main bar and having in themselves grooves for the putty into which the glasses are embedded, and moisture-trenches and a part extending between and slightly beyond the outer faces of the glasses, and a cap-plate connected to the auxiliary bars outside of and above the glasses and overlapping the edges thereof, substantially as set forth.

2. A rash-bar for greenhouses and other glazed structures, comprising a main supporting-bar of substantially U shape in cross-section, auxiliary bars of heavy bent sheet metal resting upon and carried by the main bar and having in themselves grooves for the putty into which the glasses are embedded, and moisture-trenches and a part extending between and slightly beyond the outer faces of the glasses, and a cap-plate connected to the auxiliary bars outside of and above the glasses and overlapping the edges thereof, and device, such as bolts, passing through parts of the auxiliary and main bars for firmly connecting the parts together, substantially as set forth.

3. A rash-bar for greenhouses and other glazed structures, comprising a main supporting-bar of substantially U shape in cross-section, auxiliary bars of heavy bent sheet metal resting upon and carried by the main bar and having in themselves grooves for the putty into which the glasses are embedded, and moisture-trenches formed thereof at each side of and below the line of said grooves with the free edges of the said auxiliary bars overlapping the sides of the main bar and a cap-plate connected to the auxiliary bars outside of and above the glasses and overlapping the edges thereof, and device, such as bolts, passing through parts of the auxiliary and main bars for firmly connecting the parts together, substantially as set forth.

4. A rash-bar for greenhouses and other glazed structures, comprising a main supporting-bar of substantially U shape in cross-section, an auxiliary bar of heavy bent sheet metal having central parallel adjacent portions extending through between the glasses and beyond the same with grooves upon opposite sides of said portions for the putty into which the glasses are embedded, and with moisture-trenches formed thereof at each side of and below the line of said grooves with the free edges of the said auxiliary bars overlapping the sides of the main bar and a cap-plate connected to the auxiliary bars outside of and above the glasses and overlapping the edges thereof, and device, such as bolts, passing through parts of the auxiliary and main bars for firmly connecting the parts together, substantially as set forth.

5. A rash-bar for greenhouses and other glazed structures, comprising a main supporting-bar of relatively heavy metal and substantially U form in cross-section, and auxiliary bars of heavy bent sheet metal having central parallel portions passing between the glasses of each row and extending beyond the surfaces thereof and having grooves upon opposite sides of said portions for the putty into which the glasses are embedded, and moisture-trenches formed of the material of said auxiliary bars at either side of the putty-grooves and below the plane thereof with the free edges of the auxiliary bars extending over the free edges of the main bar and overlapping the sides thereof, so that the glasses are supported on appreciable distance above the main bar, and a cap-plate outside of and above the glasses overlapping the edges thereof and connected with the auxiliary bars and means for connecting the cap-plate to the auxiliary bars and the auxiliary bars to the main bar, substantially as set forth for the purpose set forth.

897,748. DISTRIBUTOR FOR GOLD-SEPARATORS. ROBERT E. FURBERWATER, San Francisco, Cal., assignor to Edison Iron and Locomotive Works, San Francisco, Cal., a Corporation of California. Filed May 28, 1891. Serial No. 66,188. (No model.)

Claim.—1. The combination with the separator, of the distributing-box, a series of controlled outlets therein, the collecting-tables arranged below at the sides thereof, a distributor interposed between the separator and distributing-box having discharges at its respective sides, and means adjacent said respective sides on the face of the distributor for guiding the material delivered thereto to the outlets of the distributing-box for the respective collecting-tables.

2. The combination with a separator, of the distributing-box, the collecting-tables arranged below and at the sides thereof, the distributor interposed between the distributing-box and the separator, a series of oppositely-arranged inclined ribs, ridges or guides on the face of said distributor and by means of which the material fed therein is directed from the respective sides thereof toward the outlets of the distributing-box for the respective collecting-tables, and means whereby water is supplied to the distributor during the working of the separator.

3. The combination with a separator, of a distributing-box having a series of outlets, collecting-tables arranged at the sides of the distributing-box, an auxiliary distributor interposed between the separator and distributing-box having discharge-openings at its sides, and means on the face of the auxiliary distributor adjacent to the sides having the discharge-openings for guiding the material delivered thereto toward the outlets of the distributing-box for the collecting-tables; substantially as described.

4. The combination with a separator, of a distributing-box, collecting-tables arranged at the sides thereof, an auxiliary distributor interposed between the distributing-box and the separator, a series of oppositely-arranged inclined ribs, ridges or guides on the face of said auxiliary distributor by means of which the material fed thereto is directed from the respective sides thereof toward the outlets of the distributing-box for the collecting-tables; substantially as described.

5. In an apparatus of the character described, a rotary grizzly arranged to discharge from its lower portion, a distributing-box supported beneath the grizzly, collecting-tables at the sides of the distributing-box arranged to receive the discharge therefrom, and an auxiliary distributor intermediate of the grizzly and the distributing-box, the longitudinal center of the auxiliary distributor occupying a plane at one side of the plane of the longitudinal center of the grizzly, substantially as described, to enable said auxiliary distributor to catch the discharge from the grizzly thrown by centrifugal force toward said side, and deliver the same to the distributing-box for the collecting-tables.

897,749. CONTROLLING DEVICE FOR ELECTRIC MOTORS. WILLIAM B. FORTY, Schenectady, N. Y., assignor to the General Electric Company, a Corporation of New York. Filed Apr. 22, 1890. Serial No. 66,768. (No model.)

Claim.—1. A current-limiting device comprising an electromagnet in circuit with the apparatus to be protected, its coil carrying only a small

part of the current during normal working, a current-regulator, a stop for the regulator controlled by the electromagnet, and means for throwing the entire current through the magnet-coil when the current rises to a determined maximum.

2. The combination with electric motor, of a movable controller, means for locking said controller from movement, a magnet controlling said means, a shunt around the magnet-coil, and means for opening the shunt when the current in the motor-circuit rises to a given value.

3. In combination, motor and a controller, a ratchet upon the controller, and a pawl adapted to engage with said ratchet to check the movement of said controller and controlled by an electromagnet in the main circuit; with a shunt-circuit around the electromagnet controlled by a circuit-breaker the coil of which is in the main circuit.

4. The combination with electric motor, of a controller therefor, and means for checking the movement of said controller whenever a predetermined current flows through any of the motor while it is in any relation with respect to the other motor.

5. The combination with two or more electrically-connected translating devices, of a movable controller therefor, a locking device for said controller, an electromagnet for actuating said locking device, and a circuit-breaker adapted to cause the entire working current to pass through said electromagnet when said current reaches a predetermined maximum.

6. A plurality of motors, cut-out switches, and a current-limiting device; in combination with connections arranged to leave the current-limiting device always in series with at least one active motor.

7. A plurality of electric motors, a current-limiting device having coils in series with each motor, a series-parallel controller, and connections such that as the motors are thrown into series or parallel, the coils upon the current limiting device are connected in circuit in a similar relation.

8. The combination of a number of electric motors with a motor-controller, a cut-out switch for each motor, and a current-limiting device consisting of an electromagnet and a stop for the controller; the cut-outs being so connected that as any one of them is thrown, it shifts the coil of the electromagnet to the circuit of the other motor.

9. The combination with electric motor, of a current-limiting device for said motor, an electromagnet actuator for said limiting device adapted to be connected in circuit with said motor, and means whereby said electromagnet shall be operative while current flows through any motor.

10. The combination with electric motor, of a current-limiting device therefor, an electromagnet actuator for said limiting device adapted to be connected in series with any motor, and means for automatically cutting out that motor and connecting the electromagnet in another motor-circuit.

11. The combination with electric translating device of a current-limiting device for said device, an electromagnet whose coil is in circuit with said translating device, for actuating said limiting device, and cut-outs for said translating device adapted to leave the magnet-coil in circuit with a translating device still in circuit.

12. The combination with electric motor, of a controller therefor, means for checking the movement of said controller, an electromagnet in circuit with the motor for actuating said means, and cut-outs adapted to connect said magnet in another motor-circuit when the motor-circuit in which it is connected is opened.

13. The combination with electric motor, of a current-limiting device therefor, an electromagnet actuator for said limiting device, having its coil composed of two or more coils, each of which is adapted to remain connected in series with a motor in all relations of said motor with respect to said other.

14. The combination with a rotatable motor-controlling switch, of a ratchet-disk secured thereto, a pawl for said disk, an electromagnet actuator for said pawl, and means for causing sufficient of the working current to flow through said electromagnet to actuate the same, only when the working current reaches a predetermined amount.

15. The combination with electric motor, of a controller, a locking device for said controller, an electromagnet actuator for said device, and means for causing sufficient working current to flow through said electromagnet to actuate the same only when the working current reaches a predetermined maximum.

16. The combination with electric motor, of a series-parallel controller therefor, means for checking the movement of said controller, an electromagnet actuator for said means, having its coil composed of separate coils each of which is in circuit with a motor, and all of which have their relation changed by the controller with those of the motor.

17. The combination with translating device, of a current-limiting device therefor, an electromagnet actuator for said limiting device, having its coil composed of separate coils, each coil connected in series with one of the translating devices.

18. The combination with electric motor, of a controller therefor, means for checking the movement of said controller, an electromagnet in

a motor-circuit for actuating said means, and a circuit-breaker for causing an operative current through the electromagnet when the motor-current reaches a predetermined amount.

19. The combination with electric motor, of a controller therefor, means for checking the movement of said controller, an electromagnet actuator having its coil in series with one motor, a low-resistance shunt around the coil of said actuator and a circuit-breaker controlling the shunt-circuit, having its coil in series with the magnet-coil and adapted to open the low-resistance shunt when the current flowing through the motor reaches a predetermined amount.

20. The combination with a current-limiting device, of an electromagnet for actuating said device, and means for causing the working current to flow through the electromagnet when the supply-current reaches a predetermined maximum.

21. The combination with a current-limiting device, of an electromagnet for actuating said device, and a circuit-breaker adapted to cause said electromagnet to be actuated when the supply of current reaches a predetermined maximum.

22. The combination with a movable controller for translating device, of a locking device therefor, an electromagnet for actuating said device, means for actuating said electromagnet, and means for determining in advance the point at which the electromagnet shall be actuated.

23. The combination with electric motor, of a controller therefor, and means for checking the movement of said controller whenever a predetermined current flows through any one of said motors.

24. The combination with electric motor, of a series-parallel controller therefor, and means for checking the movement of said controller during its series or parallel position when a predetermined current flows through any one of said motors.

25. The combination with electric motor, of a controller therefor, means for checking the movement of said controller, an electromagnet for actuating said means, and means for diverting from a normal path to a motor a current for operating said electromagnet.

26. In combination, in a circuit containing a plurality of translating devices, means for connecting said devices either in series or in parallel, means for controlling the flow of current in said circuit, and means controlled by the current flowing in each of said devices for limiting the movement of said current-controlling means.

697,750. BRAIN-BENDER. JOHN W. FREDERICK, Chicago, Ill. Filed Nov. 4, 1903. Serial No. 26,608. (No model.)

Claim.—1. The combination with a knitter having only a single revolution to each knot, and which steps with its jaws treading in the direction of discharge of the handle, of a stationary card-supporting finger in front of the knitter, and a supplemental movable finger operated by the needle to close the slot and when so operated being located beyond the knitter but within the range of movement of its jaws, so as to prevent the outer or lower strand from escaping the knitter-jaws in the formation of the loop.

2. The combination with a knitter having only a single revolution to each knot, and which steps with its jaws treading in the direction of discharge of the handle, of a stationary card-supporting finger in front of the knitter, and a supplemental pivoted finger on one side of the slot, with its point in proximity thereto, having a talisman normally extending partially over the slot whereby it is adapted to be struck by the needle as it rises and cause its point to close the slot, said point when so operated being located beyond the knitter, but within the range of movement of its jaws, thereby preventing the outer or lower strand from escaping the knitter-jaws in the formation of the loop.

3. The combination with a knitter having only a single revolution to each knot, and which steps with its jaws treading in the direction of discharge of the handle, of a stationary card-supporting finger, a horizontal finger pivoted at one side of the slot with its point in proximity thereto and having a talisman normally extending partially over the slot whereby it is adapted to be struck by the needle as it rises and cause its point to close the slot and when so operated being located beyond the knitter but within the range of movement of its jaws, thereby preventing

ing the lower or outer strand from escaping the knitter-jaws in the formation of the loop.

697,751. FOCKER-ROSE. RICHARD F. RANDELL, Rochester, N. Y. Filed Jan. 12, 1906. Serial No. 18,571. (No model.)

Claim.—A pocket-book comprising a series of pockets, an end pocket made up of an end, back and two side pieces, the side pieces curved to the end and back, the end forming the division between the end pocket and series of pockets and having a flap extension.

697,752. FOLDING HEAD-REST. ADOLF REILL, Elmwood Park, Ill. Filed Oct. 31, 1904. Serial No. 28,661. (No model.)

Claim.—A folding head-rest comprising in combination two inverted U-shaped supports, a strip of material connected at each end to one of said supports, two pairs of bars adapted to keep the supports at a distance for disengaging the material, each pair of bars being pivoted together, and each separate bar pivoted at one end to one of the supports and at the other provided with slots adapted to engage pins on the opposite support, and cross-bars connecting the upper ends of each pair of bars, substantially as described.

697,753. SAFETY COAT-HOOK. OTTO C. STUEBE, Chicago, Ill. Assignor to William C. Burton and Charles F. Hansen, Chicago, Ill. Filed Apr. 20, 1904. Serial No. 24,795. (No model.)

Claim.—1. In a device of the class described, the combination with the two relatively movable members, one of which is provided with the corrugations, of the plunger cooperating with said corrugations, a spring co-operating with said plunger to hold it yieldingly in engagement with said corrugations, and means for holding said plunger in any position of adjustment of the two members to prevent their unassisted relative movement in either direction; substantially as described.

2. In a device of the class described, the combination with the two relatively movable members, of a lock interposed between said members to lock them from movement in either direction in any position of adjustment, and a key for said lock, said lock and said key being so constructed that the key cannot be removed unless said members are locked together; substantially as described.

3. In a device of the class described, the combination with the two relatively movable members, of a lock interposed between said members and consisting of the sliding plunger held from rotation and having the cam-lugs thereon, together with the rotating cam-piece adapted to be turned by the key and co-operating with said cam-lugs; substantially as described.

4. In a device of the class described, the combination with the two relatively movable members, one of which is provided with the corrugations, of the spring-pressed plunger co-operating with said corrugations and having the cam-lugs thereon, means for preventing the rotation of said plunger, and the rotating cam-piece adapted to be turned by the key and co-operating with the cam-lugs on said plunger; substantially as described.

5. In a device of the class described, the combination with the two relatively movable members, of a lock interposed between said members and consisting of the sliding plunger held from rotation and having the cam-lugs thereon, the rotating cam-piece adapted to be turned by the key and co-operating with said cam-lugs, the key, and the wedge adapted to prevent the withdrawal of the key except when the plunger is in locking position.

6. In a device of the class described, the combination with the two relatively movable members, one of which is provided with the corrugations, of the spring-pressed plunger co-operating with said corrugations and provided with the cam-lugs thereon, the rotating cam-piece adapted to be turned by the key and co-operating with said cam-lugs, the key, and the wedge adapted to prevent the withdrawal of the key except when the plunger is in locking position; substantially as described.

7. In a device of the class described, the combination with the two relatively movable members, of a lock interposed between said members and consisting of the cup-shaped sliding plunger held from rotation and having the cam-lugs on its edges, the cup-shaped rotating cam-piece adapted to be turned by the key and co-operating with said cam-lugs, and the expanding-spring between said plunger and cam-piece; substantially as described.

8. In a device of the class described, the combination with the two relatively movable members, of a lock interposed between said members and consisting of the cup-shaped sliding plunger held from rotation and having the cam-lugs on its edges, the rotating cam-piece adapted to be turned by the key and co-operating with said cam-lugs, the key, and the expanding-spring between said plunger and cam-piece; substantially as described.

9. In a device of the class described, the combination with the barrel having the channels 26 therein and the flange 25 at the outer end thereof, of the spring-pressed plunger adapted to slide in said barrel and having lugs 40 projecting in the channels 26 and the cam-lugs 30 thereon, the rotating cam-piece 24 having the channel 25 therein and the cam-lugs 27 thereon, words 30 having the lugs 31 thereon adapted to fit in the channels 26 of the barrel and having the elongated slots 23 therein, and the key having the notches 43 adapted to co-operate with the words and the end 35 adapted to co-operate with the channel 25; substantially as described.

697,754. AUTOMATIC SPRING-WINDING MECHANISM FOR MECHANICAL INSTRUMENT DEVICES. HERMAN E. SHARP and WILLIAM F. COOPER, Bridgeport, Conn. Filed Feb. 10, 1902. Serial No. 22,322. (No model.)

Claim.—1. In an automatic spring-winding mechanism for mechanical instrument devices, the combination of the stationary casing, the shaft journaled within said casing, the motor-spring having its inner and outer extremities respectively secured to said shaft and to the mechanism by means of which the coiling of the perforated time-sheet is effected, a wheel capable of revolution independent of said shaft, a spring relatively more powerful than the motor-spring and having its inner and outer extremities respectively secured to said wheel and to a stationary element, means—as a coil—secured to said wheel and to the pedal whereby the power-stroke of the latter will revolve the wheel in one direction to wind the more powerful spring, and a friction-clutch whereby said wheel will, when revolved in a reverse direction, be rigidly connected with said shaft to wind the motor-spring on the return movement of the pedal, substantially as set forth.

2. In an automatic spring-winding mechanism for mechanical instrument devices, the combination of the stationary casing, the shaft journaled within said casing, a motor-spring having its inner and outer extremities respectively secured to said shaft and to the mechanism by means of which the coiling of the perforated time-sheet is effected, a wheel capable of revolving independent of said shaft, a spring relatively more powerful than the motor-spring and having its inner and outer extremities respectively secured to said wheel and to a stationary element, said springs being wound in reverse directions, the pedal, a connection between said wheel and pedal whereby the power-stroke of the latter will revolve said wheel in one direction and wind said powerful spring, and a friction-clutch carried by said shaft and adapted to engage with said wheel on its reverse movement whereby at the return stroke of the pedal said powerful spring will effect the reverse movement of the wheel and thereby wind the motor-spring, substantially as set forth.

3. In an automatic spring-winding mechanism for mechanical instrument devices, the combination of the stationary casing, the shaft journaled within said casing, the motor-spring having its inner and outer extremities respectively secured to said shaft and to the mechanism by means of which the coiling of the perforated time-sheet is effected, the friction-clutch moving in harmony with said shaft, the wheel capable of independent rotation in one direction, the springs which are each relatively more powerful than the motor-spring, and which are each wound in a direction reverse to that of said motor-spring and whose inner and outer extremities are respectively secured to said wheel and to a stationary element, the pedal, and connections between said wheel and pedal whereby the power-stroke of the latter will effect the two rotations of said wheel thereby winding the powerful springs, while at the return movement of said pedal the relaxation of said powerful springs will effect the engagement of said clutches and wheels and cause the latter to revolve in a reverse direction thereby winding the motor-spring, substantially as set forth.

4. In an automatic spring-winding mechanism for mechanical instrument devices, the combination of the stationary casing, the shaft journaled within said casing, the drum loosely carried by said shaft, the motor-spring whose inner and outer extremities are respectively secured to said shaft and drum, a wheel capable of revolving independent of said shaft, a spring relatively more powerful than the motor-spring and having its inner and outer extremities respectively secured to said wheel and to a stationary element, said springs being wound in reverse directions, the pedal, a connection between said wheel and pedal whereby the power-stroke of the latter will revolve said wheel and wind said powerful spring, and a friction-clutch carried by said shaft and adapted to engage with said wheel on its reverse movement whereby at the return stroke of the pedal said powerful spring will effect the reverse movement of the wheel and thereby wind the motor-spring, substantially as set forth.

697,755. ALTERNATING-CURRENT METER. GEORGE STERN, Charlottenburg, Germany, assignor to General Electric Company, a Corporation of New York. Filed Aug. 20, 1900. Serial No. 50,000. (No model.)

Claim.—1. In combination in an induction-meter for three-phase systems, series windings included in circuit with two of the mains, and a circuit containing a short-winding connected between the third main and one of the other mains, said circuit being so organized that the current therein is displaced by thirty degrees from its impressed electromotive force.

2. In combination in an induction-meter for three-phase systems,

series windings included in circuit with two of the mains, and a circuit containing a short-winding connected between the third main and one of the other mains, said circuit being so organized that the current therein is displaced by thirty degrees from its impressed electromotive force.

3. In combination in an induction-meter for three-phase systems, series windings included in circuit with two of the mains, a short-winding connected between the third main and one of the other mains, and means in circuit with said short-winding for causing the current therein to be displaced by thirty degrees from its impressed electromotive force.

697,756. ALTERNATING-CURRENT METER. GEORGE STERN, Charlottenburg, Germany, assignor to General Electric Company, a Corporation of New York. Filed Aug. 22, 1900. Serial No. 50,000. (No model.)

Claim.—1. A three-phase alternating-current meter comprising two measuring systems in which the current flows differ in phase from one another by one hundred and fifty degrees, each of said flows being produced by the combined action of windings in circuit with two of the three-phase mains, and in which the potential flux on non-inductive load legs in one system lags behind and in the other is in advance of the corresponding current flux.

2. In a three-phase alternating-current meter, two measuring systems, each comprising current-windings connected in circuit with two of the mains and a potential winding, the current-windings being so connected and arranged that the resultant of the current fluxes in the two systems are displaced in phase from one another by one hundred and fifty degrees, and the potential windings being connected and arranged to generate on a non-inductive load a potential flux lagging by a certain angle behind the current flux in one system and a potential flux leading the current flux by the same angle in the other system.

3. In a three-phase alternating-current induction-meter, two measuring systems, each comprising current-windings connected in circuit with two of the mains, and a potential winding, the current-windings being so connected and arranged that the resultant of the current fluxes in the two systems are displaced in phase from one another by one hundred and fifty degrees and the potential windings being connected and arranged to generate potential fluxes displaced in phase from one another by the same angle, the potential flux on non-inductive load lagging in one system behind and in the other leading the current flux.

697,757. GLASS-GLIDER FOR AIR-LAMP. GEORGE E. STEVEN, Lynn, Mass., assignor to General Electric Company, a Corporation of New York. Filed Sept. 18, 1900. Serial No. 73,000. (No model.)

Claim.—1. A globe-holder for an incandescent lamp, comprising a recessed end for the neck of the glass globe, a socket for the lower end of the globe below said end, a stem detachably connected with a yoke connecting the side rods, a plurality of symmetrically-spaced pivoted clamps, and a nut threaded on the stem to adjust the clamps, said nut being below the plane of the globe-end.

2. A supporting-yoke for a globe-holder split longitudinally of its axis to form two jaws, a cylindrical socket between the jaws for the stem of the globe-holder, and a gas-arrow to compress or spread the jaws.

3. An insulated metal bushing comprising a metal tube surrounding an insulating lining and having its ends open over the edges of said lining.

4. An insulated metal bushing comprising said or more thin metal tubes surrounding an insulating lining and open at its ends over the edges of the lining.

697,758. WASHING-MACHINE. WILLIAM W. TAYLOR, Minneapolis, Minn. Filed Sept. 6, 1901. Serial No. 74,000. (No model.)

Claim.—In a washing-machine of the character herein shown, the combination in the rubber throat, of the parallel plates forming the sides thereof, the laterally-placed rubbing-bars forming the curved base or bottom thereof, wires extending laterally through the laterally-placed bars, staples driven over the said wires, between the said bars and into the said side plates, and cushions lying between the said rubbing-bars and the said side plates; said cushions being secured in place by means of the said staples, substantially as shown and for the purposes specified.

697,759. DISSEPARATOR. ANDRÉ LA BOW WALKER, Canada, E. I. Filed Jan. 2, 1902. Serial No. 60,000. (No model.)

Claim.—An agitator, comprising a receptacle having a handle, a guard extending from the lower upper edge of the receptacle on an angle toward the bottom, said receptacle having an opening under the guard, as and for the purpose described.

697,760. WINDOW-CLEANER. HENRY C. WALSH, Philadelphia, Pa., assignor of one-half to Louis V. Gray, Philadelphia, Pa. Filed July 20, 1901. Serial No. 75,000. (No model.)

Claim.—1. In a window-cleaner, a washing-strip holder consisting of a trough-shaped holder, the edges of its open side formed each with a return-bend standing obliquely toward each other within and toward the bottom of the trough to engage and form detents for the washing-strip within the holder.

2. In a window-cleaner and in combination with a chamber for containing water of a separate holder or holder of trough shape in cross-section, attached to the edges at the open side of the chamber-casing, having holes in its closed side, its edges terminating in inward-turned lips or flanges standing obliquely toward each other whereby to engage and form detents for a flexible washing-strip bound within the holder.

697,761. PLANT FOR TREATING PAPER. JULIUS WERN, Leipzig, Germany. Filed June 20, 1902. Serial No. 65,170. (No model.)

Claim.—1. In a plant for treating paper for anti-printing, the combination of means for maintaining the paper and stretching the same before the coating is applied thereto, means for applying the coating and means for maintaining and stretching and drying the same before it is rolled onto the roll substantially as described.

2. In a plant for treating paper for anti-printing the combination of means for maintaining and stretching the paper, means for applying the

coating thereto, means for drying the said coating and means for again maintaining and stretching the said paper previous to its being rolled up, substantially as described.

3. In a plant for treating paper for anti-printing, the combination of means for maintaining and stretching the paper, means for applying the coating, means for then drying the paper means for maintaining it again, a calendaring-engine to calender the paper after the second maintaining, means for drying the paper after the calendaring and for rolling the same up substantially as described.

4. In a plant of the class specified, the combination of means for maintaining and stretching the paper previous to the application of the coating, means for applying the coating, and then drying the paper, means for maintaining the paper again and a movable frame having a series of loose rolls mounted therein to stretch the paper and capable of adjustment to and from the rolling-up mechanism, and means for rolling up the paper in the manner and for the purpose substantially as described.

5. In a plant of the class specified, the combination of a paper roll, an atomizer directed toward the width of the paper, a series of stretchers to receive the paper after it has passed the atomizer, means for applying the coating to the paper and for subsequently drying the same, a second atomizer to again stretch the paper after it has been dried, stretchers mounted on an adjustable frame over which the paper is passed after the second maintaining and means for subsequently winding the paper to form a roll substantially as described.

6. In a plant of the class specified, the combination of means for maintaining and stretching the paper, means for applying the coating and subsequently drying the paper, means for again maintaining the same, a calendaring-engine and means for drying the paper after the calendaring operation, consisting of a series of sets of loose rolls, draw-rolls to pull the paper from end to end to the next set and draw-rolls to return the paper to the original size consecutively substantially as described.

7. In a plant of the class specified, the combination of a paper-roll, an atomizer to spray the paper coming from the said roll and stretchers through which the paper is passed, a device for applying the coating to the paper and means for simultaneously stretching the said coating-machine and the atomizer, means for drying the coated paper, a second atomizer and a machine for rolling up the said paper and means for simultaneously stretching the rolling-machine and the second atomizer substantially as described.

697,762. GAB-FRAME. LAURENCE WERN, Baltimore, Md. Filed Feb. 27, 1902. Serial No. 61,000. (No model.)

Claim.—1. A frame of the character described, comprising two laterally-extending wings each wing consisting of a main section, A, and a pivoted extension, B, that can be extended in alignment with and folded back against the main section; means for locking said pivoted extension in extended relation to the main section; and means for holding said foldable wings in operative position or in retracted position, as and for the purpose set forth.

2. A frame of the character described, comprising two laterally-

swinging wings spring-pressed outwardly; two links each connected at one end to one of said wings and provided at its other end with an eye; and a fast-operated tripping-lever provided at one end with a hole adapted to be inserted in said eyes whereby to hold said wings in retracted position against the action of their springs, as and for the purpose set forth.

697,768. BRUSH. ADOLF R. WIEBE, Milwaukee, Wis. Filed Jan. 16, 1902. Serial No. 1,471. (No model.)

Claim.—A multiple-tuft brush having a one-piece wood back provided with a recess back of each tuft-cocket in communication therewith but of less diameter than the same, and a plug driven through the tuft-hut in each cocket with some of the tuft material and its binding-threads into the adjacent recess.

697,764. MEANS FOR TRACING PICTURES. ED. EDGAR L. WILLIAMS, Fort St. Filed Nov. 12, 1901. Serial No. 52,942. (No model.)

Claim.—1. A multiple-tuft brush having a one-piece wood back provided with a recess back of each tuft-cocket in communication therewith but of less diameter than the same, and a plug driven through the tuft-hut in each cocket with some of the tuft material and its binding-threads into the adjacent recess.

2. A multiple-tuft brush having a one-piece wood back provided with a recess back of each tuft-cocket in communication therewith but of less diameter than the same, and a plug driven through the tuft-hut in each cocket with some of the tuft material and its binding-threads into the adjacent recess.

3. A multiple-tuft brush having a one-piece wood back provided with a recess back of each tuft-cocket in communication therewith but of less diameter than the same, and a plug driven through the tuft-hut in each cocket with some of the tuft material and its binding-threads into the adjacent recess.

4. A multiple-tuft brush having a one-piece wood back provided with a recess back of each tuft-cocket in communication therewith but of less diameter than the same, and a plug driven through the tuft-hut in each cocket with some of the tuft material and its binding-threads into the adjacent recess.

5. A means for tracing pictures, drawings or the like, comprising a frame having an opening or space through which a picture or the like may be traced and having a plurality of transfer-sheets of different colors attached to the frame at the edge of said opening, certain of said sheets being shrouded than said opening in order to pass through said opening in being turned away therefrom.

6. A means for tracing pictures, drawings or the like, comprising a frame having an opening or space through which a picture or the like may be traced, and having one or more transfer-sheets attached to the frame at the edge of said opening, said frame having a slit adjacent the edge of the opening to receive a portion of the sheet containing the picture, or the like object to be reproduced.

7. A means for tracing pictures, drawings or the like, comprising a frame having an opening through which a picture or the like may be traced and having one or more transfer-sheets attached to the frame at the edge of said opening, said frame being provided with a plurality of slots or holders adjacent the edge of the frame and adapted to engage the sheet containing the picture or the like object to be reproduced.

8. A means for tracing pictures, drawings or the like, comprising a frame having an opening through which a picture or the like may be traced, a pad consisting of leaves or blank sheets whereon the picture are traced, a strip of flexible material whereby said frame is connected to said pad at one edge, a plurality of transfer-sheets attached to said frame at one of its free edges, and suitable means for holding the picture-sheet.

697,765. RED COTTON-DYE AND PROCESS OF MAKING SAME. HENRI WINTER, Höchst-am-Main, Germany, assignor to Farbwerke, vorm. Meister, Lucius & Brüning, Höchst-am-Main, Germany, a Corporation of Germany. Filed Aug. 5, 1901. Serial No. 70,708. (Opposition.)

Claim.—1. The herein-described process for the manufacture of dyestuff for cotton, which consists in combining asymmetric this-urea, obtained by the action of asymmetric mustard-oil on 2,4,7-trinitrophenol-sulfonic acid with diamine compounds, substantially as set forth.

2. The herein-described process for the manufacture of a dyestuff for cotton, which consists in combining asymmetric this-urea obtained by the combination of an aromatic mustard-oil with 2,4,7-trinitrophenol-sulfonic acid with the diamine compound of para-aminobenzoic acid, substantially as set forth.

3. As new products, the dyestuffs having the general formula:

wherein Y is the radical of a diamine compound, X the radical of an amine of the benzene series, being brown-red powders soluble in water and which directly dye cotton red shades fast to acids.

4. As a new product, the dyestuff obtained by the action of diamine para-aminobenzoic acid on this-urea of the formula:

wherein X means the radical of an amine of the benzene series, being a brown-red powder of metallic water soluble in water to a red solution becoming blue-red on addition of mineral acid, and yellow-red on adding alkali; little soluble in alcohol; insoluble in petroleum ether; soluble in concentrated sulfuric acid, with a blue-red color; and which directly dyes cotton blue-red shades fast to acids.

697,766. FOLD-CHOPPER. HENRI K. WOOD, Hartford, Conn., assignor, by means of assignment, to the Windsor Hardware Manufacturing Corporation, Hartford, Conn., a Corporation of Connecticut. Filed Nov. 14, 1901. Serial No. 52,943. (No model.)

Claim.—1. In a fold-chopper, the combination, with a casing, of a stationary cutter having inwardly-flaring, curved teeth having a cutting edge; a screw driven a revolution of which terminates in a blunt

face, said surface curving to form the feed against the inner cutting edge of the stationary cutter; and a rotary cutter cooperating with exterior cutting-surfaces of said stationary cutter.

2. In a fold-chopper, the combination, with a casing, of a screw driven, two of the revolutions of which terminate in blunt surfaces; a stationary cutter-plate having inwardly-flaring, curved teeth against the inner sharp ends of which the feed is forced by the non-cutting end surfaces of the screw; a rotary cutter; and means for moving said rotary cutter to the feed.

3. In a fold-chopper, the combination, with a casing, of a screw driven, two of the revolutions of which terminate in blunt surfaces; a stationary cutter-plate having inwardly-flaring, curved teeth against the inner sharp ends of which the feed is forced by the non-cutting end surfaces of the screw; a rotary cutter; and means for moving said rotary cutter to the feed.

697,767. SYSTEM OF ELECTRICAL CONTROL. GRAYMAN T. WOOD AND LEONARD WOOD, New York, N. Y., assignors, by direct and means of assignment, to Henry C. Townsend and Robert H. Decker, trustees. Filed May 12, 1901. Serial No. 60,988. (No model.)

Claim.—1. The combination of a plurality of motors, a series-parallel controller therefor, and an automatically-acting current-modifying device having its movable portion in circuit with said motors, and adapted to be actuated by an abnormally great flow of current and thereby interrupt the tendency of such current to affect the normal condition or action of said motors.

2. In a system of electrical control the combination of a motor or other transmitting device, a motive switch having a stop-by-stop motion and adapted to control the current action of said motor or other transmitting device, means for placing said motive switch in communication with the source of power-supply, and an automatically-acting electromechanical device having its movable portion in circuit with said motor or other transmitting device and adapted to move and thereby interrupt the tendency of a current to affect the normal action or condition of said motor or other transmitting device.

3. In a system of electrical control the combination of a motor or other transmitting device, a motive switch having a plurality of current-carrying coils, each of which is energized independently of the other coils, a connecting-switch for electrically connecting said coils in sequence to the appropriate current-supply circuit thereby enabling said motive switch to control said motor or other transmitting device, and a spring or other device which constantly tends to snap the movable part of said connecting-switch to cut off all of said coils out of the circuit and thereby preventing the motive switch to assume its normal position.

4. In a system of electrical control the combination of a motor, a motive switch for controlling the speed of said motor, the connecting-coils

of said motive switch having one set of their terminals permanently connected together to lead current from said coils while the other set of their terminals are in a normally open circuit and a manually-operable switch which is adapted to connect the latter terminals in sequence to the open circuit terminals of the current-supply circuit, said manually-operable switch being provided with means which constantly tends to snap said latter switch to cut out of circuit all of the coils of said motive switch.

5. In an electric system the combination of a driving-motor, a speed-controlling motive switch for controlling the speed of said motor, one set of the terminals of the motive-switch-connecting coils being permanently connected together and leading to the armature of said motor while the other set of terminals of said coils are in a normally open circuit, and means for connecting the latter terminals in sequence to the current-supply circuit.

6. In an electric system the combination of a driving-motor, a motive switch for controlling the speed of said motor, a connecting-switch for controlling the action of said motive switch, a speed-controlling circuit connection between said connecting-switch and said motive switch, a driving-motor-reversing device having one terminal electrically communicating with the armature of said driving-motor and the other terminal of said device being adapted to be electrically connected to said speed-controlling circuit, and a single-point switch for controlling said motor-reversing device.

7. In combination, a motor, a controller therefor comprising fixed contacts and a movable contact, a series of oppositely-actuated devices adapted to move said movable contact step by step, in one direction, through a series of operative positions, and a connecting-switch controlling only the circuit connections which are adapted to successively operate said actuating devices to change the speed or work of said motor.

8. In an electrically-controlled system, the combination of a motor or other electrical transmitting device, a self-actuating motive switch having a plurality of independent current-carrying coils, each of which when energized influences a movable electromagnet body which is common to all of said coils, said coils being in a branch circuit in series with the motor, a contact carried by but insulated from said magnet body and adapted to change the resistance of the motor-circuit, and means whereby said coils are connected in sequence to the supply-circuit.

9. In a system of electrical control the combination of a motor, circuit therefor, a motor-speed controller, a device adapted to control the direction of rotation of said motor-armature, a single group, or set of wires whereby both of said devices are connected to said motor and an automatically-acting current-modifying device in circuit with said motor and adapted to move and interrupt the tendency of a current to affect the normal action or condition of said motor.

10. In an electrical system the combination of a motor, circuit therefor, a motive-switch device, a direction-controlling device, both of said devices being connected to said motor-circuit, a connecting-switch, means for causing the latter switch to remain in normal position when the manual control of the said latter switch ceases, and means in circuit with said motor and adapted to move automatically and interrupt the tendency of a current to affect the normal condition or action of said motor.

11. In an electrical system, the combination of a motor equipment, a motive-switch device, having a plurality of coils, all of which influence, in sequence, one and the same electromagnet body to change its position in reference to the motor-circuit and a connecting-switch adapted to connect said coils in sequence to the current-supply circuit, the said electromagnet body being free to act promptly in response to any movement of said connecting-switch.

12. In an electrical system, the combination of two sets of contacts, one set being connected to the current-supply circuit while the contacts of the other set are each connected with one wire leading to a coil of the motive switch; means for connecting one of the contacts of the latter set with the appropriate one of the former set and an automatically-acting device in circuit with a motor and adapted to move upon the flow of an abnormal current and prevent such current from changing the normal condition or action of said motor.

13. In an electrical system, the combination of a driving-motor, circuit therefor, a plurality of simultaneously-actuated contacts for effecting changes in the motor-circuit a motive switch for controlling said contacts, and a connecting-switch mechanism connected therewith and to the motor-circuit whereby when the movable part of said connecting-switch is actuated one coil of the motive switch is brought into the motor-circuit.

14. In a system of electrical control, the combination of a motor, a connecting-switch, a motive switch, and a dead-resistance connection between the motive-switch coils and the ground or return-conductor.

15. In a system of electrical control, the combination of a motor, a connecting-switch, means whereby said connecting-switch always tends to stand at open circuit, a motive switch, a high-resistance temporary connection between the motive-switch coils and the ground or return-conductor.

motor, and a low-resistance connection between said motive-switch coils and the said motor.

16. In a system of electrical control, the combination of a translating device, a commencing-switch, a motive switch, an automatically-acting device which is adapted to move under the influence of an abnormal current and interrupt the tendency of such current to interfere with normal action or condition of said translating device, and a dead-resistance temporary connection between the motive-switch coils and the ground or return-conductor.

17. In a system of electrical control the combination of a motor-controlling apparatus having a series of wire coils and adapted to control said motor, the said coils of said apparatus having one end of their terminals permanently connected together and leading to one part of their supply circuit, while the other end of their terminals are each in a normally open circuit, a manually-operable commencing-switch which is adapted to connect the latter terminals in sequence to the open-circuit terminals of their current-supply circuit, and means located at said commencing-switch whereby if the manual control of the latter switch ceases while the current is on, the circuit will be automatically opened.

18. In a system of electrical control, the combination of a motor, a commencing-switch, a motive switch, a normally open circuit connection between the motive-switch coils and the ground or return-conductor, and means whereby said circuit is closed to initially estimate said motive switch.

19. In an electrical system, a plurality of motor-controlling devices, each having its movable contacts carried by a suitable supporting apparatus, a plurality of separately-energized coils operatively related to said supporting apparatus of each controller device, each of said coils, when energized, being adapted to cause the movable contacts to move through a portion only of the full length of their path, a set of wires extending along the train and to which the said coils are connected, and a commencing-switch adapted to supply current simultaneously to the corresponding coils of the several controller devices.

20. The combination of a plurality of cars united to form a train, some of said cars being equipped with driving-motors, motor-speed-controlling apparatus upon each motor-equipped car, the motor portion of said controlling apparatus on each car being energized section by section, means on each motor-equipped car whereby the motor may be reversed, coupling-head devices on each motor-equipped car and connected with the speed-controlling apparatus and the motor-reversing means thereon, and means adapted to be coupled between the coupling-head on one motor-equipped car and a coupling-head on another motor-equipped car, whereby the corresponding sections of all of the motor-speed-controlling apparatus on the train may receive energy simultaneously by the movement of one switch, and all of said motor may be reversed at another time by the movement of another switch.

21. The combination of a plurality of cars connected up to form a train, motors upon each motor-car, some of said wires, on any given motor-car, having five terminals, the corresponding terminals of the latter wires being grouped together and then forming sets, two of said sets ending in commencing-switch apparatus, another two of said sets ending in two coupling-head devices located at the respective ends of the car, the remaining set of said terminals ending in sectionally-energized motor-controlling apparatus, and means adapted to be temporarily connected between the appropriate coupling-head device on one motor-car and a coupling-head device on another motor-car, whereby the corresponding coils of the motor-controlling apparatus on the several cars will be connected in multiple independently of the order or condition of said cars, and thereby permitting the simultaneous control of all of the driving-motors by the manipulation of either commencing-switch.

22. The combination of a motor, sectionally-energized controlling apparatus therefor, a commencing-switch to govern said controller apparatus section by section, reversing apparatus for said motor, an independent switch adapted to govern said reversing apparatus, and means located at the commencing-switch whereby the motor-circuit will be caused to be automatically opened upon failure of the motorman to control said commencing-switch during the whole time that operative current is received by said motor.

23. In a system of electrical control, the combination of a pair of motors, a commencing-switch, a speed-controlling device and a direction-controlling device, said speed-controlling device being adapted to couple said motors in series and then in parallel, and both of said devices being electrically connected to the circuit of said motors.

24. In a system of electrical control, the combination of a pair of motors, a motive-switch device having a plurality of coils all of which influence, in sequence, one and the same electromagnet body to change its position in reference to the said motors, to couple them in series and then in parallel, and a commencing-switch adapted to connect said coils in sequence to the supply-circuit.

25. In a system of electrical control, the combination of a pair of

motors, circuits therefor, a plurality of simultaneously-actuated contacts for effecting changes in the electrical connection between said motors, a motive switch for controlling said contacts, and a commencing-switch mechanism connected therewith and with the motor-circuits whereby, when the movable part of said commencing-switch is moved from one pair of its contacts to its next such pair, the resistance in said motor-circuit is thereby caused to change said motive switch being adapted to be connected in series with a motor.

26. In a system of motor control, the combination of a driving-motor, circuits therefor, sectionally-energized speed-controlling apparatus connected to the motor-circuit, a switch for governing said speed-controlling apparatus, motor-reversing mechanism connected to the motor-circuit and adapted to act only when the reversal of said motor is desired, and a switch to govern the action of said reversing mechanism.

27. In a system of motor control, the combination of a plurality of driving-motors, circuits therefor, sectionally-energized speed-controlling apparatus connected to said circuits and adapted to connect said motors in series and then in multiple, a switch for governing said speed-controlling apparatus, motor-reversing mechanism connected to the motor-circuits and adapted to constantly maintain such connection except during the reversal of said motors and a switch adapted to govern said reversing mechanism.

28. In a system of electrical control, the combination of a pair of motors, a motive switch for changing the relation of said motors from series to parallel, a commencing-switch, and a reversing device for each such motor, the coil or coils of one reversing device being in series with the coil or coils of the other such device.

29. The combination of a plurality of electrically-equipped cars, each of said cars having a driving-motor, a plurality of wires upon each car, each wire having five terminals, the corresponding terminals of the several wires upon a car being grouped together to form sets, two of said sets ending in commencing-switch apparatus, another two of said sets ending in two coupling-head devices, at the respective ends of the car, the remaining set of said terminals ending in motor-controlling apparatus, and means whereby the said terminals at the adjacent ends of two cars may be electrically connected together and the corresponding coils of the several controller devices connected in multiple and thereby permitting the simultaneous control of all of the driving-motors by the manipulation of either of said commencing-switch apparatus.

30. The combination of a circuit, and two coils or switches connected therein, one of said switches being adapted to control the other, and both having a constant tendency to automatically open the circuit.

31. The combination of a motor, a motive switch, for controlling said motor, and a single set or group of wires having five sets of terminals, two of the latter sets terminating in coupling-heads, one at each end of the car, two other of the said five sets ending in commencing-switch contacts, and wires of the remaining set of terminals being connected to the coils of the motive switch.

32. A train equipment which includes a motor or motors upon each car of such train, and a motive switch of the character described, carried by each car to control said motor or motors, each motive switch being arranged in multiple relation with each other and the other plurality of such devices being controllable upon the manual operation of one commencing-switch, said commencing-switch being adapted to be connected in series with a motor.

33. In a system of motor control, the combination of a driving-motor, circuits therefor, speed-controlling apparatus connected to the motor-circuit, a hand-switch for governing said speed-controlling apparatus, means located at said hand-switch and adapted to cause said motor-circuit to be automatically opened if the manual control of said hand-switch ceases while the motor is receiving operating-current, motor-reversing mechanism connected to the motor-circuit and adapted to constantly maintain such connection except during the reversal of said motor, and a switch for controlling said reversing mechanism.

34. In a system of electrical control, the combination of a plurality of cars, motors on some of said cars, sectionally-energized motor-controlling apparatus upon each of the motor-cars, commencing-switches for governing the motor-controlling apparatus, motor-reversing mechanism upon each motor-car and having a connection with said motors, each connection being constantly maintained except during the reversal of said motor, and means adapted to couple the motor-governing devices on one car to such devices on another car that the manual operation of any one of said commencing-switches will cause all of said motor-controlling apparatus to act simultaneously independently of the order or condition of said cars.

35. In a system of electrical control, the combination of a translating device, a commencing-switch, and a motive switch having a plurality of contacts carried by the movable part thereof and in series with the coils of the stationary part of the latter switch.

36. In a system of electrical control, the combination of a translat-

ing device, a commencing-switch, and a motive switch having a plurality of contacts carried by the movable part thereof and in series with the coils of the latter switch and also in series with said translating device.

37. In a system of electrical control, the combination of a translating device, a controlling device therefor and an automatic device acting independently of said controlling device and without disturbing the movement thereof, and adapted to proportion the energy received by said translating device to the work being done by the latter device.

38. A train of electrically-equipped cars, each car having a commencing-switch and a reversing-switch at each end thereof, means for coupling said cars together so that the several cars may be operated simultaneously from any one of the several commencing-switches, motive switches, one upon each car, circuit connections between the commencing-switches and the motive switches whereby all of the latter switches may be controlled by any one of the former switches, and means carried by each car, said means being governed by each appropriate motive switch as herein described.

39. In an electrically-equipped train system, the combination of means to drive the train, a self-actuating motive-switch device upon each car and adapted to change the connection of the car-motors from series to multiple and vice versa, two commencing-switches upon each car, each such latter switch being adapted to cause the several motive switches to simultaneously adjust the motor under their control, a motor-reversing device on each car and means upon each car whereby the several reversing devices may be controlled from any car on the train.

40. In an electrically-equipped train consisting of "added units" or a series of independently-equipped cars, the combination of a plurality of motors for each car, a motor-controlling switch on each car to control the said motors thereon, a motor-reversing means upon each car, means whereby the several motors upon the train may be adjusted simultaneously from any car of the train, and means adapted to move automatically and acting independently of any of said apparatus to prevent the power-current from causing an abnormal action or condition of said motor.

41. A train of cars each equipped with a motor to drive it, a common controlling device for the motors, means which tend to hold said device out of the circuit, and means acting independently of the said motor and without disturbing any of the controlling apparatus to check any tendency of the power-current to cause the motor to become abnormal.

42. A train with one car each individually equipped with a pair of driving-motors initially coupled together in series, and a current-varying controller therefor, the motor on each car being initially coupled in multiple series with respect to those on the other cars, and means whereby said controller are always caused to move synchronously and inductively, thereby the connections of the several pairs of motors are simultaneously changed from series to multiple.

43. In a system of electrical control, the combination of driving-motors, a motive switch having a series of independently-energizable coils, and a commencing-switch adapted to control said motive switch, the contacts carried by said motive switch being insulated from each other and from the parts of said motive switch upon which said contacts are mounted.

44. In a system of electrical train control, the combination of a plurality of cars each having a driving-motor, motor-controlling apparatus upon each such car, and means adapted to electrically connect any given point of each controller apparatus with the corresponding point of each of the other of said controller apparatus.

45. In a system of electrical train control, the combination of a plurality of cars each having a driving-motor, motor-controlling apparatus upon each such car, means adapted to electrically connect the motor-controlling apparatus on one such car to such apparatus on another car so that a given point of one controller apparatus will be in electrical connection with the corresponding point of each of the other controller apparatus.

46. In a system of electrical control, the combination of a plurality of cars each having a motor to drive it, a motor-speed controller upon each such car, a commencing-switch for each speed-controller and means adapted to couple the said electrical apparatus on one car to such apparatus on an adjacent car, means adapted to cause all of said speed-controllers to simultaneously and synchronously change the action of said motor.

47. In a system of electrical control, the combination of a plurality of electrical conductors, a plurality of motors connected between said conductors, motor-control apparatus in electrical communication with said conductors, and means adapted to be energized section by section and thereby cause said control apparatus to change the relation of said motors from series to parallel.

48. In a system of electrical control, the combination of a plurality of conductors, a plurality of motors, connected between said conductors, a motor-control apparatus in electrical communication with said conductors, means adapted to be energized section by section and thereby cause

said control apparatus to change the relation of said motors from series to parallel, and means adapted to reverse said motor.

49. The combination of a plurality of electrically-equipped cars, a motor-controlling device upon each such car, means adapted to electrically connect the motor-controlling device on the car to such device on an adjacent car, and means adapted to cause all of said controlling devices to start simultaneously and move with a synchronously step-by-step motion.

50. In an electrical system, the combination of plurality of cars, each having two commencing-switches thereon, a commencing-switch or operator's line on each such car and connected between the two said switches thereon, and branches from said switch-line and adapted to electrically connect the commencing-switches on one car with such devices on the adjacent car independently of any other electrical circuit.

51. An electrically-equipped car having in combination, a motor, controlling apparatus therefor, a plurality of commencing-switches, one each for the respective ends of the car, a group of wires connected between said commencing-switches, a plurality of coupling-heads, one each for the respective ends of the car, each of said heads having all of its connecting fingers or terminals arranged in a vertical series, and appropriate connections between said fingers or terminals and said group of wires.

52. An electrically-equipped car having in combination, a motor, controlling apparatus therefor, a plurality of commencing-switches, one each for the respective ends of the car, a group of wires connected between said commencing-switches, a plurality of coupling-heads, one each for the respective ends of the car, each such head having all of its connecting fingers or terminals arranged in a vertical series, and appropriate connections between said fingers or terminals and said group of wires, the arrangement being such that a given wire will be connected to fingers or terminals in the respective coupling-heads, which have the same relative position when the said two series of fingers or terminals are compared.

53. The combination of a plurality of cars, each having a motor to drive it, a motor-controller for each car, and means adapted to electrically connect the corresponding points of all the controllers.

54. The combination of a plurality of cars, each having a motor to drive it, a motor-controller for each car, means adapted to deliver electrical energy simultaneously to the corresponding points of all the controllers and means adapted to reverse said motor.

55. In a motor-controller, the combination of a plurality of coils adapted to be successively energized, and means external to the finally-energized coil and adapted to maintain a minimum current in the latter coil.

56. In motor-control apparatus, the combination of a plurality of individually-actuated coils, and a branch circuit therefrom and in series with the motor.

57. In motor-control apparatus the combination of a plurality of individually-actuated coils having a branch circuit in series with the motor, and contacts moved by said coils.

58. The combination of a motor, a plurality of individually-actuated coils having a branch circuit in series with said motor, and a commencing-switch adapted to estimate said coils.

59. The combination of a motor, and controller apparatus, the coils of the latter apparatus having a branch circuit in series with said motor, and another branch circuit in parallel with said motor.

60. A car, a driving motor or motors thereon, a circuit therefor, a plurality of movable contacts for effecting changes in the motor-circuit, means adapted to operate said movable contacts, and a commencing-switch connected therewith and communicating with a branch circuit which is in series with said motor.

61. A plurality of cars, a plurality of driving-motors on each car, a set of fixed contacts and a set of movable contacts for effecting changes in the circuits of the motors, means adapted to estimate said movable contacts, and commencing-switches on the several cars and connected with the contact-estimating means and communicating with a branch circuit which is in series with the motor.

62. A plurality of cars, a plurality of driving-motors for each car, a plurality of contacts for reversing said motor, means adapted to estimate said contacts, means adapted to connect the electrical apparatus on one car to that on an adjacent car, commencing-switches communicating with said contacts, and means adapted to be energized section by section to connect the motors in series and in multiple.

63. A plurality of cars, a plurality of driving-motors for each car, a plurality of contacts for reversing the motors, means adapted to estimate said contacts, means adapted to connect the electrical apparatus on one car to that on an adjacent car, commencing-switches communicating with said contacts, and means adapted to be energized section by section to connect the motors in series and in multiple and to vary the resistance in circuit therefor.

64. The combination of a plurality of motors, a plurality of fixed contacts and a movable contact, means controlled thereby for changing

the grouping of the motors from series to parallel and vice versa, and electromagnets apparatus energized section by section to control said means.

65. A plurality of cars, driving-motors upon a number of such cars, movable contacts for changing the circuit connections of the said motors to vary the work performed thereby, means energized section by section to control said contacts, means adapted to connect the electrical apparatus on one car to such apparatus on another car, and one or more connecting-switches for controlling said movable contacts.

66. The combination of one or more connecting-switches each provided with a plurality of contacts, a plurality of motors, and controller apparatus adapted to connect said motors in series and then in multiple, the said controller apparatus being provided with a set of fixed contacts and a plurality of movable contacts and adapted to have one motion energized to move said movable contacts one step when the connecting-switch makes connection with one of its contacts.

67. The combination of a plurality of motors, a controller apparatus therefor, and a connecting-switch adapted to govern the controller apparatus section by section, the said controller being so arranged and connected that it will automatically open the motor-circuit upon the failure of the line-current.

697,768. GAS AND AIR MIXING BURNER. WILLIS J. WOODWARD, Indianapolis, Ind. Filed Sept. 4, 1901. Serial No. 74,385. (No model.)

Claim.—1. A gas and air mixing burner comprising draft-tubes having each an external screw-thread at the lower end thereof and also having at the opposite or upper end thereof draft-tubes formed with the bottom thereof extending inwardly and upwardly from the outer surface of the tube to the edge of the top adjacent to the lower end of the tube where the perforations in said bottom plate are engaged by the threads on said tubes whereby the same are supported, a top plate having perforations in which said tubes may rotate, and a wall connecting said plates.

2. In a gas and air mixing burner, the combination with the perforated top plate and the perforated bottom plate, of the screw-threads in the perforations in said bottom plate, and the draft-tubes having the external screw-threads engaging the screw-threads in said perforations and also having each the draft-tubes with the bottom thereof extending inwardly and upwardly from the outer surface of the tube to the edge of the top adjacent to the lower end thereof, said draft-tubes extending into the perforations in said top plate.

3. The herein-described burner-tube consisting of a hollow cylinder the upper end of which has the grooves formed with the bottom thereof extending inwardly and upwardly from the outer surface of the tube to the edge of the top adjacent to the lower end thereof, and the lower end of which has the external screw-thread formed thereon.

4. In a gas and air mixing burner, the combination of the bottom plate having the apertures therein, the screw-threads in said apertures, the top plate having the apertures therein, the draft-tubes having the screw-threads engaging and supported by the screw-threads in said apertures and having the upper ends thereof movably inserted in the apertures in said top plate, and the air-drafts and the gas-drafts in said tubes, substantially as set forth.

697,769. CASTING APPARATUS. ALFRED M. ASKIN, Pittsburgh, Pa. Filed Jan. 20, 1901. Serial No. 45,307. (No model.)

Claim.—1. The combination with a traveling carrier, provided with a series of molds, and a furnace, of a means for conducting molten metal from the furnace to said molds, continuously and at constant or regulated speed, comprising a trough interposed between said carrier and furnace and normally so related thereto as to constitute a stationary guide for conducting metal from the furnace to the molds approximately without interruption in the flow thereof, said trough having its forward end in communication with the furnace-spout so as to receive metal therefrom and constructed and arranged to discharge continuously into said molds, and, being constructed, rearward of its said metal receiving and discharging end, to form a reservoir for the accumulation therein of excess metal under abnormal conditions, and means for adjusting said trough so as to cause the metal to be conducted to the molds as rapidly as it flows from

the furnace, or cause a regulated portion of the metal to be diverted from the discharge end of the trough and be detained in said reservoir, or to cause metal in the reservoir to flow into said discharge end.

2. The combination with a traveling carrier, provided with a series of molds, and a furnace, of a means for conducting molten metal from the furnace and discharging the same continuously and at constant or regulated speed into the molds, comprising a trough pivoted near its front end and interposed between said furnace and molds, said trough having an approximately plane bottom and approximately triangular sides, and having its forward end arranged in communication with the furnace-spout so as to receive the metal therefrom and arranged to discharge into the molds continuously, said forward end terminating in a constructed pouring-lip, the rear portion of said trough constituting a reservoir which is normally arranged to detain metal of the metal flowing from the furnace, and means connected with the rear end of the trough for adjusting the inclination of the latter so as to cause a regulated quantity of the metal to be diverted from the metal-receiving end thereof into said reservoir, or to cause metal in the reservoir to flow therefrom into said receiving end, substantially as described and for the purposes set forth.

3. The combination with a continuously-rotated carrier, provided with a series of molds, and a furnace having continuously-open communication with its spout of a means for conducting molten metal from the furnace and discharging the same continuously and at constant or regulated speed into the molds, comprising a pivoted trough interposed between said furnace and carrier, having its forward end in communication with the furnace-spout so as to continuously receive molten metal therefrom and arranged to discharge metal continuously into the molds, said trough being constructed rearward of its said metal receiving and discharging end, to form a reservoir which is normally arranged to detain metal of the metal flowing from said furnace, and means for adjusting said trough so as to cause a regulated portion of the metal to be diverted from said forward end thereof into said reservoir, or to cause metal from said reservoir to flow into said forward end, substantially as described and for the purposes set forth.

4. The combination with a pivoted device designed to receive molten metal from a furnace and having a pouring-lip at one end, and an endless carrier projecting to beneath said lip at one end, of a series of flat molds arranged in a step-by-step relation upon said carrier and each having an end overlapping that of the one next adjacent, said parts being so related that when a mold has reached a position where it directly receives the flow from said lip the one approaching said position will have assumed a horizontal plane to retain an overflow, substantially as described.

5. The combination with a pivoted device designed to receive molten metal from a furnace and having a pouring-lip at one end and disposed constantly to discharge the metal and, when the speed is normal, discharging said metal approximately so fast as the metal is delivered to it, and having a reservoir portion, and means for adjusting the inclination of said device when the speed is abnormal and to accord therewith, and an endless carrier projecting to beneath said lip at one end, of a series of flat molds arranged in a step-by-step relation on said carrier and each having an end overlapping that of the one succeeding it, said parts being so related that when a mold has reached a position where it directly receives the flow from said lip the one approaching said position will have assumed a horizontal plane to retain an overflow, all substantially as described and for the purposes set forth.

697,770. AUTOMATIC INJECTOR. CHARLES R. ALLER, Wabash, Ind. Filed Feb. 1, 1908. Serial No. 52,211. (Model.)

Claim.—1. An injector, having an overflow-chamber with two or more overflows therein, and an opening to the atmosphere from said chamber arranged at a point above the level of the rear overflow.

2. In an injector, a single overflow-chamber containing two or more overflows, and a combining-tube, the forward overflow being at a point in the rear of the smallest diameter of said tube a distance equal to at least twice said diameter.

3. In an automatic injector of the class described, the combining-tube, the forcing-tube, a series of overflows x , y and z in a single chamber, and an atmosphere overflow above the series of overflows and provided with a check-valve, combined and arranged so that the series of overflows must be submerged before water can issue from the atmospheric overflow and of all other things the check-valve under vacuum action in the chamber above the atmospheric overflow.

4. In an automatic injector of the class described, the tube t having an adjustable angular head, and the tube q also having an adjustable angular head, an intermediate overflow-chamber having two or more overflows and an opening to the atmosphere arranged above the level of the rearward overflow.

5. An automatic injector of the class described, having a combining-tube interposed between the overflow-chamber and the boiler connection, and provided with a series of lateral holes near its side of a combined area not greater than one and six-tenths of the smallest cross-sectional area of said tube, and serving as an intermediate overflow, and a series of holes of similar capacity arranged forward of the intermediate overflow-holes and near the smallest diameter of the tube, substantially as described.

697,771. ANIMAL-SERRARE. RAYMOND W. ALLER, Chicago, Ill. Filed Aug. 7, 1901. Serial No. 71,354. (No model.)

Claim.—1. In a shearing-machine the combination with a frame, vibrator, vibrator-rod, and means for actuating the vibrator, of means additional to the stud for supporting the vibrator in operative position.

2. In a shearing-machine the combination with a frame, vibrator, vibrator-rod, and means for actuating the vibrator, of means for supporting the vibrator located between its stud and the means by which the vibrator is operated.

3. In a shearing-machine the combination with a frame, vibrator-rod, vibrator, and means for operating the vibrator, of a flat-bottomed room in the frame, and a rocker provided with a convex head, located in the room and supporting the vibrator.

4. In a shearing-machine the combination with a frame, vibrator-rod, vibrator, and means for actuating the vibrator, of two pairs of jaws upon the vibrator, and a tension-lever resting in said jaws and operatively connected thereby with the vibrator.

5. In a shearing-machine the combination with a frame, vibrator-rod, vibrator, and means for actuating the vibrator, of an externally

spherical collar upon the vibrator, a tension-lever provided with a corresponding bearing, and means for assembling the parts.

6. In a shearing-machine, the combination with a frame, vibrator-rod, vibrator, and means for actuating the vibrator, of a tension-lever carried by the vibrator, a nut on the stud, and ball-bearing members between the tension-lever and nut.

7. In a shearing-machine the combination with a frame, vibrator-rod, vibrator, and vibrator-actuating mechanism, of an externally spherical collar upon the vibrator, a tension-lever provided with a corresponding bearing, a block upon said bearing around the stud, an annulus, intermediate ball-bearings between the annulus and the block, and a nut working against the annulus on the threaded extremity of the stud.

8. In a shearing-machine the combination with a frame, vibrator-rod, vibrator, and vibrator-actuating mechanism, of an externally spherical collar upon the vibrator, a tension-lever provided with a corresponding bearing, a block upon said bearing around the stud, an annulus, intermediate ball-bearings between the annulus and the block, a nut working against the annulus on the threaded extremity of the stud, and a sleeve surrounding the annulus and block.

697,772. SAFETY CONTROLLER AND INDICATOR FOR ELEVATORS. CHARLES R. ALLER, Port Carbon, Pa. Filed July 12, 1901. Serial No. 68,154. (No model.)

Claim.—1. The combination in a device of the character described, of the winding-drum, braking means applied thereto, a movable piston for controlling said braking means, an indicating-dial, and means controlled by said dial for throwing the piston into action under certain conditions, substantially as described.

2. The combination in a device of the character described, of the winding-drum, braking means applied thereto, a movable piston adapted to actuate said braking means, a valve for controlling the movement of said piston, an indicator-dial, a tripping-lever controlled by said dial and a connection between said tripping-lever and the valve whereby the latter may be opened when the tripping-lever is released by the dial.

3. The combination in a device of the character described, of the winding-drum, braking means carried thereby, a lever connected to said braking means, a movable piston controlling said lever, an indicator-dial, means for operating said dial in unison with the winding-drum, a tripping-lever supported out of action by the indicator-dial, and a connection between said tripping-lever and the piston-valve whereby the latter may be operated when the tripping-lever is released by the dial.

4. The combination in a device of the character described, of the winding-drum, braking means applied thereto, a movable piston for controlling said braking means, an indicator-dial, means for rotating said dial in unison with the movement of the winding-drum, and a tripping-lever supported out of action by said indicator-dial, said dial having a weighted portion into which the lever may fall under certain conditions and when in such position will operate the piston-valve of the braking mechanism and the throttle-valve of the braking-cylinder.

5. The combination in a device of the character described, of the winding-drum of a hoisting-engine, braking means applied thereto, a movable piston for controlling said braking means, a valve controlling the movement of said piston, an indicator-dial controlled and operated in unison with the winding-drum, and a tripping-lever normally held in contact with said dial by means of a suitable spring, said dial having a notch into which the tripping-lever may be pulled under certain conditions, and when in such position operating the piston-valve and the throttle-valve of the engine.

6. The combination in a device of the character described, of the winding-drum of a hoisting-engine, braking means applied thereto, a movable piston for controlling said braking means, a valve controlling the movement of said piston, an indicator-dial controlled and operated in unison with the winding-drum, a tripping-lever normally held in contact with said dial by means of a suitable spring, said dial having a notch into which the tripping-lever may be pulled under certain conditions, and when in such position operating the piston-valve and the throttle-valve of the engine, and means for returning said tripping-lever to its normal position whereby the automatic braking mechanism may be reset, substantially as described.

7. In a device of the character described, a dial for use in connection therewith, a tripping-lever controlled by said dial, said dial having a notch to receive said tripping-lever, and adjustable pieces for regulating the width of said notch.

8. The combination in a device of the character described, of the winding-drum, braking means applied thereto, a movable piston for controlling said braking means, an indicator-dial, means controlled by said dial for throwing the piston into action under certain conditions, and means for returning the movement of said piston, substantially as described.

697,778. TARKLEY, JOHN F. ALGERHATTY and DANIEL T. VAN TINE, Australia, Wash. Filed July 6, 1901. Serial No. 67,861. (No model.)

Claim.—The combination, in a roll paper holder and covering device, of a roller adapted to receive a roll of paper and having bearings formed in its ends, a frame formed of spring-wire extending across and above the roll of paper and having its central portion bent to form a substantially inverted V-shaped offset and having its ends bent downward to form side arms, said side arms having plates adapted to spring into the said bearings, a transversely-curved plate provided adjacent to one end with downwardly-extending ears having an opening to receive the wire frame whereby the plate is pivotally mounted, a spring coiled on the frame about the said offset portion and having its extremities bearing against the under side of the said plate, and an upwardly, rearwardly-curved handle extension formed integral with the rear side of the transversely-curved plate whereby the said roller may be raised or lowered.

697,774. APPARATUS FOR AMAYING ORNS. WILLIAM T. AMSTERDAM, San Jose, Cal. Filed Jan. 20, 1902. Serial No. 90,051. (No model.)

Claim.—1. The combination in an apparatus for amaying orns, of a receptacle having a suitable closure, and an ore-containing envelop or cap of fibrous material adapted to be inserted into said receptacle whereby the ore is prevented from coming in contact with the sides of said receptacle during the process of reduction.

2. The combination in an apparatus for amaying orns, of a tubular receptacle having a removable closure, and an ore-containing envelop or cap of fibrous material adapted to be inserted into said receptacle.

3. The combination in an apparatus for amaying orns, of a tubular structure of heat-resisting material, closed at one end and having a perforated removable cover or cap on the other end, and an ore-containing receptacle or cap adapted to telescope within said tubular structure.

4. In an apparatus for amaying orns, the combination of a tube having one end closed and a removable perforated cap fitting the other end

of the tube, said tube having a lining of material which carbonizes during reduction.

697,775. RAIL-JOINT. PAUL BARAN, New Kensington, Pa. Filed Jan. 12, 1902. Serial No. 30,092. (No model.)

Claim.—1. In a rail-joint, a chair having a fish-plate formed integral therewith, and a second fish-plate secured to said chair, independent wedges engaging between one of said fish-plates and the webs of the rails, and foot extensions carried by the outer ends of said wedges, said foot extensions extending beyond the ends of the fish-plate and chair, engaging the base of the rail and secured to the tie, substantially as described.

2. In a rail-joint, a chair having a fish-plate, formed integral therewith, and a second fish-plate carried by the chair and engaging the webs of the rails, independent wedges engaging between said first-named fish-plate and the webs of the rails, and means carried by the said wedges adapted for engagement with the base of the rails secured to the tie, substantially as described.

697,776. ROLLER FOR WINDING PAPER ON FASTBOARD TUBES. EDWARD J. BARKER, Morgan Park, Ill. Filed Dec. 12, 1901. Serial No. 30,093. (No model.)

Claim.—1. A roller for winding paper on tubes having a longitudinal shoulder on their inner circumference, which has such construction as to prevent an opposing edge to said shoulder.

2. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, which is provided with a longitudinal shoulder adapted to oppose the shoulder of said tube, when revolving.

3. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, which is provided with a longitudinal shoulder by reducing the circumference of the roller adjacent to its shoulder, which latter is adapted to oppose the shoulder of said tube when revolving.

4. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, which is provided with a longitudinal shoulder by making its circumference conform to a spiral plane, that is adapted to oppose the shoulder of said tube when revolving.

5. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference comprising a wooden body so constructed as to present an opposing edge to said shoulder, and metallic ferrules on the ends thereof.

6. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, comprising a wooden body which is provided with a longitudinal shoulder adapted to oppose the shoulder of the tube when revolving, and metallic ferrules on the ends thereof.

7. A roller for winding paper on paper tubes having a longitudinal

shoulder on their inner circumference, comprising a wooden body which is provided with a longitudinal shoulder by reducing the circumference of the roller adjacent to its shoulder, which latter is adapted to oppose the shoulder of the tube when revolving, and metallic ferrules on the ends thereof.

8. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, comprising a wooden body which is provided with a longitudinal shoulder by making its circumference conform to a spiral plane which shoulder is adapted to oppose the shoulder of said tube when revolving, and metallic ferrules on the ends thereof.

9. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, comprising a wooden body so constructed as to present an opposing edge to said shoulder, and metallic ferrules on the ends thereof beyond the circumference of which said edge projects.

10. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, comprising a wooden body which is provided with a longitudinal shoulder adapted to oppose the shoulder of the tube when revolving, and metallic ferrules on the ends thereof, beyond the circumference of which said shoulder projects.

11. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, comprising a wooden body which is provided with a longitudinal shoulder by reducing the circumference of the roller adjacent to its shoulder which latter is adapted to oppose the shoulder of the tube when revolving, and metallic ferrules on the ends thereof, beyond the circumference of which said shoulder projects.

12. A roller for winding paper on paper tubes having a longitudinal shoulder on their inner circumference, comprising a wooden body which is provided with a longitudinal shoulder by making its circumference conform to a spiral plane which shoulder is adapted to oppose the shoulder of said tube when revolving, and metallic ferrules on the ends thereof, beyond the circumference of which said shoulder projects.

697,777. PARLOR-CAR CHAIR. ALLEN F. BARNET, Washington, D. C. Filed Dec. 2, 1901. Serial No. 30,312. (No model.)

Claim.—1. In a railway-car seat, the combination with the seat, the swinging back and a supporting-pedestal, of means for guiding the seat vertically and device for raising and lowering the seat with said by the swinging movement of the back from one position to another, substantially as set forth.

2. In a railway-car seat, the combination with the seat, the swinging back and a supporting-pedestal, of means for guiding the seat vertically, device for raising and lowering the seat with said by the swinging movement of the back from one position to another, and steps for limiting the movement of the back in both directions, substantially as set forth.

3. In a railway-car seat, the combination with the pedestal, of a seat and frame and a guide-post connected therewith and vertically movable in the said pedestal, a back and swinging arm connected therewith and supports therefor adapted to rotate with the seat, and device connected to and acting with said arm for raising and lowering the seat with the movement of the back, substantially as set forth.

4. In a railway-car seat, the combination with a chair pedestal, of a device surrounding the upper part thereof and having radial opposite arms, arms pivotally connected to the above said arms and a swinging back pivotally connected to their upper ends and arm-arms projecting from and preferably integral with the said pivoted arm near their lower ends, a guide-post turning in and vertically movable in said pedestal, a frame carried thereby, a seat-frame connected therewith, arm-frames connected to opposite sides of the seat-frame and rising therefrom and having steps or lugs at their respective ends adapted to engage the pivoted arms of the back, the guide-post, its frame, the seat-frame, seat and arm frames sub-

stantially in the manner and for the purposes set forth.

5. In a railway-car seat, the combination with the pedestal, of a seat and frame and a guide-post connected therewith and vertically movable in the said pedestal, a back and swinging arm connected therewith, and supports therefor adapted to rotate with the seat, and arm-arms projecting from and preferably integral with the said swinging arm near their lower ends and acting with the movement of the said arm for raising and lowering the seat, substantially as set forth.

6. In a railway-car seat, the combination with the seat, the swinging back and a supporting-pedestal, of means for guiding the seat vertically, device for raising and lowering the seat with said by the swinging movement of the back from one position to another, and steps for limiting the movement of the back in both directions, and device substantially as specified for changing the relation of the back and seat in the raised and depressed positions of the seat to decrease the depth of the seat in the depressed position and increase the space between the back and seat, substantially as set forth.

7. In a railway-car seat, the combination with the seat, the swinging back and a supporting-pedestal, of means for guiding the seat vertically, device for raising and lowering the seat with said by the swinging movement of the back from one position to another, and steps for limiting the movement of the back in both directions, the steps at one side being farther from the vertical center than at the other side to cause the relative positions of the back and seat to one another to be changed with the change from the elevated to the depressed position to shorten the depth of the seat, substantially as specified.

697,778. WARDROBE. ALLEN F. BARNET, Washington, D. C. Filed Dec. 2, 1901. Serial No. 30,093. (No model.)

Claim.—1. The combination with a supporting-beam placed transversely of a room and secured to the walls thereof adjacent to the ceiling, a frame extending around the room and located adjacent to the ceiling, and means for securing the same in place, of a wardrobe device or receptacle comprising sides, ends and a bottom portion, and fitting within the space bounded by said beam and frame hinges for connecting the wardrobe device at one end to the supporting-beam, and means connected to the other end and engaging the said frame for supporting the wardrobe in a horizontal position of the end opposite to the hinges, substantially as set forth.

2. The combination with a supporting-beam placed transversely of a room and secured to the walls thereof adjacent to the ceiling, a frame extending around the room and located adjacent to the ceiling, and means for securing the same in place, of a wardrobe device or receptacle comprising sides, ends and a bottom portion, hinges for connecting the same at one end to the supporting-beam, means connected to the other end and

engaging the said frame for supporting the wardrobe at the end opposite to the hinges, and spring devices existing in returning the wardrobe device to and supporting the same in a normally horizontal position, substantially as set forth.

3. The combination with a supporting-beam placed transversely of a room and secured to the walls thereof adjacent to the ceiling, a frame extending around the room and located adjacent to the ceiling, and means for securing the same in place, of a wardrobe device or receptacle comprising sides, ends and a bottom portion, hinges for connecting the same at one end to the supporting-beam, means connected in the other end and engaging the said frame for supporting the wardrobe at the end opposite to the hinges, spring devices existing in returning the wardrobe device to and supporting the same in a normally horizontal position, and means for imparting to the wardrobe or receptacle a longitudinal movement simultaneously with the swinging movement, substantially as set forth.

4. A wardrobe device adapted to fit up against the under side of the ceiling of a room, comprising a supporting-beam secured in place, a frame surrounding the sides of the room and occupying a position parallel with the ceiling, one or more wardrobe-receptacles fitting within the frame, and device for hinging the same at one end to the means of support and at the other end for removably connecting the same to the frame, whereby the under surface of the wardrobe device, and the frame form a substitute for the ceiling, substantially as set forth.

5. The combination with an inverted-T supporting-beam placed centrally and transversely of a room and at its ends connected to and supported by the side walls, of a frame of boards parallel with the ceiling fitting within the room and coming below the said beam, means for supporting the said frame in place, wardrobe devices or receptacles each comprising sides, ends and bottom portions paneled, undermost channels or slideways in the outer faces of the sides, channel-bars received therein and provided with T-head members at one end, hinges connecting said members at one end with the inverted supporting-beam, spring devices connected to said beam and also to the other ends of said T-head members, means secured to the other ends of the wardrobe devices and connecting with the free ends of the channel-bars for longitudinally moving the wardrobe devices with reference to the channel-bars whereby said wardrobe devices may swing downward and also longitudinally of the channel-bars and may be returned to place and means for suitably supporting the wardrobe devices with reference to the frame, substantially as set forth.

6. The combination with an inverted-T supporting-beam placed centrally and transversely of a room and at its ends connected to and supported by the side walls, of a frame of boards parallel with the ceiling fitting within the room, and coming below the said beam, means for supporting the said frame in place, wardrobe devices or receptacles each comprising sides, ends and bottom portions paneled, undermost channels or slideways in the outer faces of the sides, channel-bars received therein and provided with T-head members at one end, hinges connecting said members at one end with the inverted supporting-beam, spring devices connected to said beam and also to the other ends of said T-head members, a shaft placed transversely of the wardrobe device at the opposite end and drums on the ends of said shaft, steel tapes or equivalent devices connected at one end to the free ends of the channel-bars and at their other ends to said drums, means for rotating the said shaft and drums and holding the same in position, and a device connected to the wardrobe structure and adapted to engage the frame when the wardrobe is diverted to position, substantially as set forth.

697,779. AME-GARE. NATHAN BARNET, New York, N.Y. Filed July 10, 1901. Renewed Mar. 13, 1902. Serial No. 97,508. (No model.)

Claim.—1. In a cart, the combination with the body portion, of a cover adapted to loosely rest thereon and having slats adapted to normally maintain said cover in place, said cover having inclined sides, one or more openings in said inclined sides of said cover, a plurality of covers for said openings, and springs adapted to normally hold said last-mentioned covers closed, substantially as described.

2. In a cart, the combination with the body portion thereof of a detachable cover resting upon said body portion and having one or more openings therein, normally closed covers for said openings, and a detachable foot-board carried by said body portion below said openings, substantially as described.

3. In a cart, the combination of the body portion pivoted upon the frame of the cart, a cover for said body portion, a tail-board at the rear of said body portion, one or more openings in said cover, spring-pressed covers for said openings, and a detachable foot-board carried by said body portion below said openings, substantially as described.

697,780. PEDAL FOR VELOCEPHEDE. JAMES H. BARRY, London, England. Filed Oct. 5, 1901. Serial No. 77,714. (No model.)

Claim.—1. In a folding pedal, a crank-arm having a slot in its outer end, a spindle having a head pivoted in said slot, a recess in said head and a movable part in said crank-arm adapted to engage said recess; substantially as described.

2. In a folding pedal, the combination with a crank-arm having a slot in its outer end; of a spindle having a head pivoted in said slot, a recess in said head and a movable part in said crank-arm adapted to engage said recess; substantially as described.

3. In a folding pedal, the combination with a crank-arm having a slot in its outer end; of a spindle pivoted in said slot and having a recess therein, and a sliding bolt on said crank-arm adapted to engage said recess; substantially as described.

4. In a folding pedal, the combination with a crank-arm having a slot in its outer end; of a spindle pivoted in said slot and having a recess therein, and a sliding bolt on said crank-arm having a nose adapted to engage said recess; substantially as described.

5. In a folding pedal, the combination with a crank-arm having a slot, a spindle pivoted in said slot and having a recess therein; of a sliding bolt on said crank-arm, and a nose on said sliding bolt adapted to enter said slot and engage said recess in said spindle; substantially as described.

6. In a folding pedal, the combination with a crank-arm having a slot, a spindle pivoted in said slot and having a recess therein; of a sliding bolt on said crank-arm, a pin on said sliding bolt adapted to enter said slot and engage said recess in the spindle, and a knob on said sliding bolt; substantially as described.

697,781. SAFETY COAT-HOOK. WILLIAM C. BARTON and CHAS. F. HAMMON, Chicago, Ill. Filed Feb. 9, 1901. Serial No. 44,619. (No model.)

Claim.—1. In a device of the class described, the combination with the stationary hook, of the locking-piece adapted to be moved down over the hook, a locking mechanism between said hook and piece to hold the parts from movement in either direction in any position, said mechanism comprising the ratchet-teeth on the hook and a locking-bolt movable to and from said teeth; substantially as set forth for the purpose described.

2. In a device of the class described, the combination with the base-piece having ways formed therein, the serrations between said ways and a hook projecting therefrom, of a locking-piece adapted to slide in said ways and cooperate with the hook and locking mechanism carried by said

locking-piece and cooperating with said serrations to hold said base-piece and locking-piece in any position of adjustment.

3. In a device of the class described, the combination with the base-piece having ways formed therein and a serrated channel between said ways, a hook projecting therefrom, of a locking-piece adapted to slide in said ways and cooperate with the hook, and a screw-threaded locking-ping in said locking-piece having a point adapted to be screwed into one of the serrations of the channel.

4. In a device of the class described, the combination with the base-piece having ways formed therein and a serrated channel between said ways, a hook projecting from said base-piece, of a locking-piece adapted to slide in said ways and cooperate with the hook, and a screw-threaded locking-ping in said locking-piece having a point adapted to be screwed into one of the serrations of the channel and having a special recess adapted to receive the blade of a key by which it is turned.

5. In a device of the class described, the combination with the base-piece having ways formed therein, the serrations between said ways and a stationary hook projecting from bottom thereof, of a locking-piece adapted to slide in said ways cooperating with the hook, and having the hook; projecting from said locking-piece, and locking mechanism carried by said locking-piece, and cooperating with said serrations to hold said base-piece and locking-piece in any position of adjustment.

6. In a device of the class described, the combination with the base-piece having ways formed therein and a serrated channel between said ways, a hook projecting from the bottom thereof, of a locking-piece adapted to slide in said ways and cooperate with the hook, a hat-hook; projecting from the upper part of said locking-piece, a screw-threaded locking-ping in said locking-piece having a point adapted to be screwed into one of the serrations of the channel and provided with a special recess adapted to receive the blade of a key.

697,782. INSULATOR. ADOLPH E. BROS and EDWARD E. BROS., Chicago, Ill. Filed Aug. 10, 1901. Serial No. 72,609. (No model.)

Claim.—1. As an improved article of manufacture, an insulator having a longitudinal slot to receive the edge or rim of a canopy and provided with a recess into which a portion of the canopy may be bent, substantially as described.

2. As an improved article of manufacture, an insulator comprising a piece having a longitudinal slot, an opening on its inner portion communicating with said slot, and a recess on the inner wall of the outer portion of the insulator and registering with said opening, substantially as described.

697,783. DYNAMO-ELECTRIC MACHINE. HENRY J. BROS, Schenectady, N.Y., assignor to the General Electric Company, a Corporation of New York. Filed Aug. 26, 1900. Serial No. 728,000. (No model.)

Claim.—1. A dynamo-electric machine provided with slotted copper bridges between the poles.

2. A dynamo-electric machine provided with pole-pieces and slotted copper plates under the pole-corners.

3. A dynamo-electric machine provided with pole-pieces and slotted plates, or bodies of conducting material under the pole-corners.

4. A dynamo-electric machine provided with pole-pieces, a plate or body of conducting material extending between pole-pieces, and a plurality of openings or holes in said plate or body.

5. A dynamo-electric machine having field-magnets, and slotted bridges of conducting material under the pole-tips and extending between the poles.

6. A dynamo-electric machine having field-magnets and slotted bridges of non-magnetic conducting material extending between the poles of the field-magnets.

7. A dynamo-electric machine having two relatively rotatable members, one of which is provided with teeth and the other with opening slots closed at the ends and of the same pitch and width as the slots between the teeth of the first member.

8. A dynamo-electric machine provided with pole-pieces carrying slotted bodies of conducting material under the pole-tips.

9. A dynamo-electric machine provided with pole-pieces and bodies of slotted conducting material arranged to intercept the lines of force flowing through the pole-tips.

697,784. CAN-BODY-ENDING MACHINE. HENRY C. BLAKE, Oakland, Cal. Filed June 14, 1901. Serial No. 64,548. (No model.)

Claim.—1. In a can-body-ending machine, the combination with the oppositely-rotating disks, of seats formed in the periphery of said disks, the drive-shaft, means whereby a step rotation is imparted to the oppositely-rotating disks, the tapered pruner-plates for applying the ends to the can-bodies, devices carried by the drive-shaft whereby the pruner-plates are operated to apply the ends, and means for supplying the can-bodies and ends to the machine.

2. The combination in a can-body-ending machine, of the oppositely-rotating disks, of a series of can-body seats formed in the periphery of each disk, of means for imparting a step rotation to the said disks, and device whereby the ends are forced onto the can-body during the step rotation of the said disks.

3. The combination with the oppositely-rotating disks which receive and hold the can-bodies during the operation of ending the same, of a series of can-body-holding seats formed in the periphery of each disk, a peripheral slotted drive-disk, device for imparting a step rotation to the oppositely-rotating disks through the medium of the said drive-disk, and means whereby the ends are applied to the can-body during the step rotation of the disks.

4. The combination with the oppositely-rotating disks, of means for imparting a step rotation thereto, the tapered pruner-plates for forcing the ends onto the can-body held and carried by the oppositely-rotating disks, and means by which the pruner-plates are actuated during the step rotation of the said disks.

5. In a can-ending machine, the combination with the oppositely-rotating disks which receive and hold the can-bodies, the drive-shaft, device actuated by the drive-shaft for imparting a step rotation to the oppositely-rotating disks, the tapered pruner-plates by means of which the ends are applied to the held can-body, and can device carried by the drive-shaft for operating the pruner-plates.

6. The combination with the oppositely-rotating disks for receiving and holding the can-bodies during the operation of ending the same, of means whereby a step rotation is given to said disks, the spring-pressed tapered pruner-plates for applying the ends onto the can-bodies, and means for actuating the pruner-plates during the step rotation of the receiving and holding disks.

697,785. CAN-BODY FORMING AND GOLDENING MACHINE. HENRY C. BLAKE, Oakland, Cal. Filed June 14, 1901. Serial No. 64,549. (No model.)

Claim.—1. In a can-body forming and soldering machine, the combination with the endless carrier, of means whereby a non-reciprocating intermittent travel is imparted thereto, a series of expansible canner-horns carried thereby, mechanism whereby can-body blanks are fed to and rolled directly upon the canner-horns, and means actuated during the movement of the endless carrier for expanding the canner-horns.

2. In a can-body forming and soldering machine, the combination with an endless carrier, of means for imparting a non-reciprocating intermittent movement to the carrier, a series of expansible canner-horns carried thereby, device by means of which can-body blanks are rolled upon the canner-horns, the soldering-iron beneath which the can-bodies are carried, the roller-feed mechanism, means for expanding the canner-horns and holding same expanded while traveling beneath the soldering-iron, and device actuated by the can-body carried upon the canner-horn for controlling the feed of the solder to the soldering mechanism.

3. The combination with the endless carrier, of means for imparting a non-reciprocating intermittent travel thereto, a series of expansible canner-horns carried thereby, of means whereby can-body blanks are rolled upon the canner-horns, of means whereby the can-bodies are carried, the soldering-iron beneath which the can-bodies are carried, and device for holding down the top edge of the can-bodies as carried beneath the soldering mechanism.

4. The combination with the endless carrier, of means for imparting an intermittent non-reciprocating travel thereto, a series of canner-horns delivered to the endless carrier, of means whereby can-body blanks are fed to and rolled directly upon the canner-horns, soldering mechanism beneath which the rolled can-bodies are carried, means actuated during the movement of the carrier for expanding the canner-horns as they approach the soldering mechanism, and device whereby the canner-horns are thrown into a horizontal position as they approach the feed mechanism and so held during travel through the machine.

5. The combination with the endless carrier, of means for imparting an intermittent travel thereto, a series of expansible canner-horns carried to the endless carrier, of means whereby can-body blanks are fed to and rolled around the canner-horns, the soldering mechanism, means actuated during the travel of the carrier whereby the horns and the body-blanks rolled thereupon are expanded during travel toward the soldering mechanism and held expanded while carried thereunder and means operated by the held can-bodies whereby solder is fed to the soldering mechanism as the can-bodies move thereunder.

6. The combination with the endless carrier, of means for imparting an intermittent non-reciprocating travel thereto, a series of canner-horns attached to and carried by the endless carrier, of means whereby can-body blanks are rolled directly upon the canner-horns, soldering mechanism

beneath which the rolled can-bodies are carried, and device by means of which the top edge of the can-bodies are held down as carried beneath the solder mechanism.

7. The combination with the endless carrier, of means for imparting an intermittent non-reciprocating movement thereto, a series of canner-horns hinged to and carried by the endless carrier, of means for rolling can-body blanks around the canner-horns, of soldering mechanism, means for holding down the top edge of the can-bodies as carried beneath the soldering mechanism, and device actuated during the travel of the endless carrier for expanding the canner-horns as carried toward the soldering mechanism.

8. The combination with the endless carrier, of means by which the carrier is driven with an intermittent movement, a series of canner-horns delivered to and carried by the carrier, of device for placing the canner-horns into horizontal alignment and so holding the same while traveling through the machine, of mechanism whereby can-body blanks are fed to and rolled around the canner-horns, the soldering device, of means actuated during the travel of the endless carrier by means of which the canner-horns and body-blanks rolled thereon are expanded as the horns move toward the soldering device, of means for supplying solder thereto, and device actuated by the can-body upon the horns during travel of the carrier and by which is operated the solder-supplying means.

9. The combination with the endless intermittently non-reciprocating traveling carrier, of a series of expansible canner-horns secured to and carried thereby, means whereby can-body blanks are fed to and rolled around the canner-horns, an eccentric cam arranged within each canner-horn, a crank-arm attached to said cam, device located in the path of travel for the canner-horn whereby the crank-arm is actuated during travel of the endless carrier to throw the eccentric cam so as to expand or permit of its canner-horn being contracted, soldering mechanism beneath which the rolled can-bodies are during travel of the endless carrier, and means actuated by the can-bodies during the travel of the carrier for feeding solder to the soldering mechanism.

10. The combination with the endless carrier, of means for imparting an intermittent non-reciprocating travel thereto, a series of expansible canner-horns hinged to and carried by the endless carrier, of means whereby can-body blanks are fed to and rolled directly upon the canner-horns, and a gage-shoulder carried by each horn and against which the under lap of the rolled can-body blank bears.

11. The combination with the endless carrier, of means for imparting an intermittent non-reciprocating travel thereto, a series of canner-horns hinged or delivered to and carried by the endless carrier, of means whereby can-body blanks are fed to and rolled upon the canner-horns, means for expanding the canner-horns and its body-blanks rolled thereon during travel of the endless carrier, the soldering mechanism, and device by means of which the expanded bodies are held firmly to the horns as carried beneath the soldering mechanism.

12. The combination with the endless carrier, of means for imparting an intermittent non-reciprocating travel thereto, a series of expansible canner-horns hinged to and carried thereby, of means whereby can-body blanks are rolled directly upon the canner-horns, the soldering mechanism, the wire-solder feed, and device actuated by the can-bodies during travel of the canner-horns and by means of which the solder-feed is operated to feed the wire solder to the soldering mechanism.

697,786. COMBINED BOTTOMER AND CRIMPER FOR CAN-BODIES. HENRY G. BLACK, Oakland, Cal., assignor to Axel Johnson, Oakland, Cal. Filed June 14, 1901. Serial No. 94,860. (No model.)

Claim.—1. The combination with the receiving and retaining disks which receive and hold the can-bodies, of device for imparting movement thereto, means whereby a bottom is applied to the can-body while held by the said disks, and mechanism by means of which the open head end of the can-body is crimped.

2. The combination with the receiving and retaining disks which receive and hold the can-bodies, each disk being provided with a series of seats in the periphery, of device for imparting a step rotation to the said disks, means whereby slight longitudinal movement is given to the retaining-disks, means whereby bottoms are applied to the can-bodies held between the disks, and mechanism whereby the open head end of the can-body is crimped while the bottom is forced thereon.

3. The combination with the carrier-disks which receive and hold the can-bodies, of means for imparting a step rotation to the carrier-disks, crimping-rolls, device whereby the crimping-rolls are moved in and out of the can-body to be crimped, means for imparting rotation to the said rolls, device whereby the crimping-rolls are expanded after insertion within the can-body, and means whereby bottoms are applied to the can-bodies while the open head end thereof is being crimped.

4. The combination with the carrier-disks which receive and hold the can-bodies, of device for imparting a step rotation to said disks, of

means whereby bottoms are forced onto the held can-bodies, the crimping-rolls by means of which the head end of the can-bodies are crimped while held by the carrier-disks, a rotating piston by which the rolls are carried, device whereby reciprocating movement is imparted to the said piston, an expander working through the piston and by means of which the crimping-rolls are forced against the inner wall of the can-body, and means whereby the expander is moved in and out of the piston of the crimping-rolls.

5. In a combination with the receiving-disks, of the retaining-disks, the side bearing-blocks within which the shaft of the retaining-disks work, device whereby the side bearing-blocks are forced inward and the retaining-disks moved against the receiving-disks during the operation of crimping the can-bodies and away from said disks after the bodies have been crimped, means for imparting a step rotation to the receiving and retaining disks, mechanism whereby the head end of the can-body is crimped, and device for moving the crimping mechanism in and out of the can-bodies.

6. The combination with the receiving and retaining disks which receive and hold can-bodies during the operation of applying bottoms thereto, of the feed-chutes for the can bodies and bottoms, a series of seats for the can-bodies cut in the periphery of each disk, means for imparting a step rotation to the said disks, a piston by means of which the bottoms are forced onto the can-bodies, and device actuated by the drive-shaft of the machine by which the piston for applying the bottoms is moved inward and outward.

7. The combination with the receiving-disks, of the retaining-disks which cooperate therewith, of device for imparting a step rotation to the receiving and retaining disks, and mechanism whereby the retaining-disks are moved horizontally toward and from the receiving-disks.

8. The combination with the receiving-disks, of the retaining-disks which cooperate therewith, a series of can-body seats cut or formed in the periphery of each disk, of device for imparting a step rotation to the receiving and retaining disks, mechanism whereby the retaining-disks are moved horizontally toward and from the receiving-disks, the crimping-rolls which work within the head end of the can-body held within the seats of the said disks, device whereby the crimping-rolls are moved in and out of the can-body.

9. The combination with carrying mechanism for the can-bodies, of crimping-rolls for crimping the end of the can-bodies, a rotary piston to which the crimping-rolls are elastically attached, means whereby the piston is moved inward and outward during its rotation so as to place the crimping-rolls in or out of the can-bodies, and means for expanding the crimping-rolls when moved within the open end of the can-bodies.

697,787. DOWELLING-MACHINE. JOHN J. BLACKMAN, New Britain, Conn. Filed Jan. 2, 1902. Serial No. 93,940. (No model.)

Claim.—1. The combination, with a movable work-support, of means for clamping material upon said work-support; cutters shaped to form re-

cesses and counterpart intermediate projections in the work; and means for actuating said cutters, the said cutters disposed in sets, arranged to operate within different areas of the work, and the cutters of one set being proportioned to those of the others, so that the recesses produced by the former shall correspond to the projections produced by the latter.

2. The combination, with a movable table, of means for clamping sections of material to said table; a series of cutter-spin-dies, recessing-cutters secured to said spin-dies; said cutters being disposed in sets arranged to operate within different areas of the work, and the cutters of one set being proportioned to those of the others, so that the recesses produced by the former shall correspond to the projections produced by the latter.

3. In a dovetailing-machine, the combination, with a table, of gear-work for reciprocating said table; means for clamping sections of material in which counterpart dovetail recesses and projections are to be formed to said table; a series of sets of cutters one set forming one series of recesses and projections in one section of material, and another set a different series of recesses and projections in the other section of material; spin-dies to which said cutters are secured; means for rotating the spin-dies; and a support for said spin-dies.

4. In a dovetailing-machine, the combination, with a reciprocating table, of means for securing sets of blocks in which a certain number of dovetail recesses are to be formed to one portion of said table; means for securing sets of blocks in which a different number of dovetail recesses are to be formed to another portion of said table; a set of cutter-spin-dies; cutters carried by said spin-dies for forming dovetail recesses in the first-named set of blocks; a second series of cutter-spin-dies; cutters carried by said second series of cutter-spin-dies for forming dovetail recesses in the second set of blocks; means for actuating the cutters; and means for actuating the table.

5. In a dovetailing-machine, the combination, with a reciprocating table, of strips upon said table; an abutment at one end of the table; clamps for forcing sections of material placed between the strips against said abutment; means for reciprocating the table; sets of cutters disposed to operate within different areas of the work; and the cutters of one set being proportioned to those of another set, so that the recesses produced by one set of cutters shall correspond to the projections produced by another set of cutters; and means for rotating the cutters.

6. In a dovetailing-machine, the combination, with a table, of strips dividing said table into a series of compartments; means for clamping sections of material upon said table; means for actuating the table; a series of sets of cutters for recessing the material, said sets arranged to operate, respectively, within different areas of the work, and the cutters of one set being proportioned to those of the other set, so that the recesses produced by one set will correspond to the projections produced by another set; and means for rotating the cutters.

7. In a dovetailing-machine, the combination, with a frame having ways, of a table mounted on said ways; means for reciprocating the table; a frame located over the table and having a guideway on each of its sides; a series of heads adjustably mounted on the guideway on one side of said frame; a series of adjustable heads fitted to the guideway on the other side of said frame; spin-dies mounted in the heads; recessing-cutters carried by the spin-dies; means for rotating the cutters; and means for clamping material upon the reciprocating table.

8. The combination, with a movable support for maintaining and feeding the material, of means for actuating said support; a frame located at each side of said support; spin-dies carried by the frame; levers pivoted to each end of said frame; pressure bars or rollers connecting said levers, and means for actuating the levers to cause said pressure bars or rollers to bear against the material on the support.

9. The combination, with a movable support for maintaining and feeding material, of means for actuating said support; a frame located over said support and having a guideway on each of its sides; a series of heads

adjustably mounted on each of said guideways; spindles journaled in the heads; cutters carried by the spindles; means for rotating the spindles; presser bars or rollers movably mounted on said frame; and means for causing said presser bars or rollers to bear against the material on the support.

10. The combination, with a support for sustaining material, of a frame located over said support; cutters, and means for actuating the same carried by said frame; presser bars or rollers movably mounted on the frame and located on each side thereof; means for actuating said presser bars or rollers to cause them to bear against the material on the support; an intermediate presser bar or roller carried by the frame; and means for forcing said intermediate bar or roller against the work upon the support.

11. The combination, with a support, of means for actuating said support; a frame adjustably mounted over said support and having a guideway on each of its sides; a pair of levers pivoted to each end of said frame, each lever having a long arm and a short arm; presser bars or rollers carried by the long arms of said levers; lugs on the frame at each end thereof; a spring for forcing the short arms of the levers against said lugs; heads adjustably mounted on the guideways of the frame; cutter-spindles carried by said heads; and means for actuating the cutter-spindles.

12. The combination, with framework having guideways, of a table mounted on said guideways; strips for dividing said table into compartments; means for securing material in said compartments; means for re-presenting the table; a frame mounted over said table; means for adjusting said frame; a series of heads adjustably mounted on the frame; spindles journaled in the heads; means for rotating the spindles; cutters carried by the spindles; presser bars or rollers; and means for causing said presser bars or rollers to bear with yielding pressure against the material on the table.

697,788. METALLURGICAL CRANE. DAVID W. BLAIR, Perth Amboy, N. J., assignor of one-half to James C. McCoy, Perth Amboy, N. J. Filed Jan. 17, 1900. Serial No. 90,114. (No model.)

Claim.—1. A metallurgical crane, comprising a member to be disposed over a metallurgical bath and adapted to be lifted, a plurality of longitudinal shafts connected with said member and free to slide endwise, and hooks connected with said shafts and adapted to engage electrodes, the arrangement being such that said hooks are free to engage said electrodes when said shaft is shifted endwise.

2. A metallurgical crane, comprising a member disposed over a metallurgical bath and adapted to be lifted, a plurality of shafts journaled to said member and normally free to shift endwise, and L-shaped hooks connected with said shafts, the arrangement being such that said hooks can be brought into engagement with the electrodes by the longitudinal movement of said shafts.

3. A metallurgical crane, comprising a member to be lifted, a plurality of longitudinal shafts connected therewith and free to slide endwise and also to rock radially, and hooks connected with said shafts; the arrangement being such that said hooks may be brought into simultaneous engagement with a particular class of electrodes, and then by longitudinal and lateral movements of said shafts, brought into simultaneous engagement with a separate class of said electrodes.

4. A metallurgical crane, comprising a member located over a metallurgical bath and adapted to be lifted, a plurality of longitudinal shafts connected therewith and free to move endwise and also free to rock, a plurality of L-shaped hooks connected with said shafts, the hooks upon either shaft all being disposed in the same plane and having their bills extended in the same direction; the arrangement being such that said hooks can all be rocked simultaneously, and can also be moved simultaneously in the general direction in which the bills extend, for the purpose of engaging electrodes.

5. A metallurgical crane, comprising a frame to be located over a metallurgical bath having anodes and cathodes disposed alternately, a plurality of shafts mounted upon said frame, a plurality of hooks connected

with said shafts, said hooks being free to rock in planes extending across said bath, and also free to move in the general longitudinal direction of said bath; the arrangement being such that said hooks are free to simultaneously engage all of said anodes, or to simultaneously engage all of said cathodes, as desired.

6. A metallurgical crane, comprising a frame to be located over a metallurgical bath having anodes and cathodes disposed alternately, a plurality of shafts mounted upon said frame, and a plurality of L-shaped hooks connected with said shafts, all the hooks of each shaft being disposed in the same plane and normally having their bills turned in the same direction, said hooks being free to rock in planes extending across said bath, and also free to travel in the general longitudinal direction of said bath; the arrangement being such that said hooks are free to simultaneously engage all of said anodes, or to simultaneously engage all of said cathodes, as desired.

7. A metallurgical crane, comprising a member to be disposed over a metallurgical bath and adapted to be lifted, and rows of hooks adapted to engage electrodes, said hooks being free to move in the general direction of said rows and also to move transversely to said rows, whereby to engage electrodes.

697,789. GAS-GENERATOR FOR GAS-ENGINE. GEORGE W. BROWN, Fremont, Cal. Filed Aug. 12, 1901. Serial No. 71,708. (No model.)

Claim.—1. In a gas-generator, a heating-plate having a continuous passage formed on the surface thereof, a plurality of outlets from said passage, all located adjacent to one edge of the heating-plate, and means for controlling said outlets; substantially as described.

2. In a gas-generator, a heating-plate having a boundary-flange and a series of parallel ribs extending alternately from opposite sides or ends of said boundary-flange and terminating at points short of the opposite sides, whereby a continuous passage is constructed, a plurality of outlets located adjacent to one edge of the heating-plate, one in each space formed by the shortening of the alternate ribs at said edge, and means for controlling said outlets; substantially as described.

3. In a gas-generator, a casing comprising a flat heating-plate formed with a continuous passage on its upper surface, and constituting the bottom of said casing, said walls secured to said plate, an inlet through one of the side walls, a removable cover *c*, and an outlet through said cover; substantially as described.

4. A gas-generator comprising a heating-plate, a chamber above the same having a suitable inlet and outlet, a box *D* located immediately below the heating-plate, a division-wall *d'* in said box, an inlet into said box through the bottom thereof at one side of said division-wall and an outlet at the opposite side thereof, a chamber *B* adapted to contain a heating medium located directly below the box *D* and having two exhausts, one registering with the opening in the bottom of the box and the other registering with the exhaust from said box, and a controlling-damper in the chamber *B*; substantially as described.

5. A gas-generator comprising a heating-plate, a chamber above the same having a suitable inlet and outlet, a box *D* located immediately below the heating-plate, a division-wall *d'* in said box having the laterally-extending shield-plate *d''* as inlet into said box through the bottom thereof at one side of said division-wall and an outlet at the opposite

side thereof, a chamber E adapted to contain a heating medium located directly below the box D and having two exhausts, one registering with the opening in the bottom of the box and the other registering with the exhaust from said box, and a controlling-damper in the chamber E; substantially as described.

697,790. PYROXYLIN COMPOUND. JEAN R. G. BERNARD, Belgium. Filed Nov. 11, 1901. Serial No. 51,948. (No specimens.)

Claim.—1. The process of making pyroxylin compounds which consists in adding to a pyroxylin solution, a solution made by dissolving gum-copal in boiling castor-oil.

2. The process of making pyroxylin compounds which consists in adding to a solution of pyroxylin, a solution composed of gum-copal dissolved in boiling castor-oil, mixed with sugar of lead, white copperas, and litharge.

3. The process of making pyroxylin compounds, which consists in adding to a pyroxylin solution, a solution composed of gum-copal dissolved in boiling castor-oil, sugar of lead, white copperas, litharge, and a small quantity of vanilla.

4. The process of making pyroxylin compounds which consists in dissolving nitrocellulose in methylated alcohol and campher, and adding to the solution thus obtained, a solution composed of gum-copal dissolved in boiling castor-oil, and of sugar of lead, litharge, white copperas, and adding a small quantity of vanilla.

697,791. BURNINGHOOD. DONALD L. BURNAL, New York, N. Y. Filed Oct. 13, 1901. Serial No. 73,417. (No model.)

Claim.—A device of the class described comprising two members a hinged together at b, said device being adapted to be secured to and to inclose the hoof of a horse, the connection with the hoof being such that the point where the separate members a are hinged together is, when the device is connected with the hoof, at the central front portion of said hoof, said members being also provided at their rear ends with projecting jaws by which they are secured to the hoof, said jaws being arranged in pairs and the bottom pair being set inwardly further than the upper pair, and said separate members being also provided at the bottom thereof with inwardly-directed flanges or supports to which a shoe may be secured, one of the members being also provided at each end with a projection adapted to enter a corresponding socket or recess in the ends of the other member, substantially as shown and described.

697,792. PROCESS OF VULCANIZING RUBBER. AUGUSTUS C. BROWN, Bristol, R. I. Filed Jan. 2, 1902. Serial No. 22,572. (No specimens.)

Claim.—1. The within-described process of vulcanizing articles made of rubber compounds, consisting in subjecting the articles to heat

and pressure in an atmosphere of a gas having an affinity for sulfur compounds, that will neutralize these compounds injurious to rubber, substantially as set forth.

2. The within-described process of vulcanizing rubber articles, consisting in subjecting the articles to heat and pressure in an atmosphere of volatilized ammonium salt, substantially as set forth.

3. The within-described improvement in vulcanizing articles of rubber under heat and pressure, consisting in heating the articles, together with a volatilizable substance having an affinity for sulfur compounds, in a closed chamber, substantially as set forth.

4. The within-described improvement in vulcanizing articles of rubber under heat and pressure, consisting in heating the articles, together with a volatile ammonium salt, in a closed chamber, substantially as set forth.

5. The within-described improvement in vulcanizing articles of rubber under heat and pressure, consisting in heating the articles in a closed chamber, together with a volatilizable substance having an affinity for sulfur compounds, in proper quantity to produce when volatilized the desired pressure in said chamber, substantially as set forth.

697,793. PNEUMATIC HAMMER. JOSEPH BUTER, St. Louis, Mo., assignor to Chicago Pneumatic Tool Company, a Corporation of New Jersey. Filed Nov. 12, 1900. Renewed Jan. 4, 1901. Serial No. 62,121. (No model.)

Claim.—1. A pneumatic hammer comprising a cylinder formed at its front end to receive the shank of the working tool and having a grasping-handle secured to its rear end, a valve-chamber separate from the piston-chamber in said cylinder and located at the rear end thereof, two longitudinal passages in the cylinder-wall communicating at their rear ends with the motive-fluid supply and with the valve-chamber, respectively, a piston-controlling valve located in the valve-chamber, and a hammering-piston located in the piston-chamber and operating at its forward stroke to place the front ends of the two longitudinal passages in communication with each other and thereby admit motive fluid to the valve-chamber to shift the valve in one direction, and operating at its rearward stroke to cut off such communication and open the exhaust from the valve-chamber to permit the valve to be shifted in the opposite direction, substantially as described.

2. A pneumatic hammer comprising a cylinder formed at its front end to receive the shank of the working tool and having a grasping-handle secured to its rear end, a valve-chamber separate from the piston-chamber in said cylinder and located at the rear end thereof, two longitudinal passages in the cylinder-wall communicating at their rear ends with the motive-fluid supply and with the valve-chamber, respectively, a piston-

being provided with two longitudinal passages opening at their forward ends into the smaller portion of the piston-chamber and at their rear ends communicating, respectively, with the motive-fluid supply and with the larger area of the valve, the stem of the piston controlling the ports at the forward ends of said passages and operating at the forward stroke of the piston to place them in communication with each other and at its rearward stroke to cut off communication between them and open the exhaust from the larger area of the valve, substantially as described.

22. In a pneumatic hammer, the combination of a cylinder containing a piston-chamber having a forward portion of less diameter than its rear portion, a differential piston located in said chamber, and a differential valve located in a chamber at the rear end of the piston-chamber and controlling the inlet and exhaust of the motive fluid at the rear end of the piston-chamber, to the smaller area of which valve the motive fluid is constantly admitted and to the larger area of which it is intermittently admitted, said cylinder being provided with two passages opening at their forward ends into the smaller portion of the piston-chamber and at their rear ends communicating, respectively, with the motive-fluid supply and with the larger area of the valve, and the piston operating at its forward stroke to place the former of such passages in communication with the passage leading to the larger area of the valve and with the larger portion of the piston-chamber, and operating at its rearward stroke to cut off such communication and open the larger area of the valve to the exhaust, substantially as described.

23. In a pneumatic hammer, the combination of a cylinder containing a piston-chamber having a forward portion of less diameter than its rear portion, a differential piston located in said chamber, and a differential valve located in a chamber at the rear end of the piston-chamber and controlling the inlet and exhaust at the rear end of the piston-chamber, to the smaller area of which valve the motive fluid is constantly admitted and to the larger area of which it is intermittently admitted, said cylinder being provided with two longitudinal passages opening at their forward ends into the smaller portion of the piston-chamber and at their rear ends communicating, respectively, with the motive-fluid supply and with the larger area of the valve, and also provided with an exhaust-passage opening at its forward end into the smaller portion of the piston-chamber and at its rear end into the larger portion thereof, and the piston operating at its forward stroke to close said exhaust-passage and to place the motive-fluid passage in communication both with the front end of the large piston-chamber and with the passage leading to the larger area of the valve, and operating at its rearward stroke to cut off such communication and to open both the front end of the large piston-chamber and the larger area of the valve to the exhaust, substantially as described.

24. In a pneumatic hammer, the combination of the cylinder A containing the differential-piston chamber, the piston fitting therein and composed of the head H, stem I, and intermediate reduced portion J, the valve-chamber located at the rear end of the cylinder A and containing the differential-piston valve O, the handle B having the inlet-passage D and exhaust-passage Q, the former of which is in constant communication with the smaller area of the valve O, and both of which are alternately placed in communication with the rear end of the piston-chamber by the movement of the valve, the cylinder A being also provided with the two longitudinal passages L and K, both opening at their forward ends into the smaller portion of the piston-chamber, and the former communicating at its rear end with the inlet-passage D and the latter communicating at its rear end with the larger area of the valve, and the front ends of said passages being placed in communication at the forward stroke of the piston by the interposition between them of the reduced portion J of the piston, the rearward stroke of the piston cutting off such communication by the interposition between them of its stem I, and opening the front end of the passage L to the exhaust, substantially as described.

25. In a pneumatic hammer, the combination of the cylinder A containing the differential-piston chamber, the piston fitting therein and composed of the head H, stem I, and intermediate reduced portion J, the valve-chamber located at the rear end of the cylinder A and containing the differential-piston valve O, the handle B having the inlet-passage D and exhaust-passage Q, the former of which is in constant communication with the smaller area of the valve O, and both of which are alternately placed in communication with the rear end of the piston-chamber by the movement of the valve, the cylinder A being also provided with the two longitudinal passages K and L, both opening at their forward ends into the smaller portion of the piston-chamber, and the former communicating at its rear end with the inlet-passage D and the latter communicating at its rear end with the larger area of the valve, said cylinder being also provided with a third longitudinal passage opening at its forward end into the smaller portion of the piston-chamber and at its rear end into the larger portion thereof, and the portions I and J of the piston serving to control the forward ends of all three of said passages, in the manner and for the purpose described.

897,794. MOLD FOR CASTING BRAKE-SHOES. ARTHUR L. BRAKE, Toronto, Canada. Filed Sept. 10, 1906. Serial No. 690,022. (No model.)

Claim.—1. A mold, comprising a drag, a sand mold therein provided with a series of connected mold-cavities, detachable partitions inserted vertically edgewise in the sand at the sides of the mold-cavities and partially separating the same into individual mold-cavities, and a plate-cope covering the upper edges of the partitions and mold-cavities, and shaped to conform to the adjacent faces of the articles to be cast; substantially as described.

2. A mold comprising a drag, a sand mold therein provided with a series of mold-cavities, and a metallic plate-cope covering said sand mold and having a portion of its surface over the several mold-cavities provided with a permanently attached non-metallic composite material to prevent chilling the adjacent face of the casting; substantially as described.

3. A mold, comprising a drag, a sand mold therein, a detachable metal partition within the mold and dividing the same into a plurality of mold-cavities, and a plate-cope shaped to conform to a portion of the contour of the article to be cast, said cope having its under or mold face composed partly of metal and partly of non-metallic material, substantially as specified.

4. A mold, comprising a drag, a sand mold therein divided into a plurality of mold-cavities, and a plate-cope shaped to conform to a portion of the contour of the article to be cast, said plate having its under or mold face composed partly of metal chilling-surfaces and partly of a composition of fire-clay and graphite, substantially as specified.

5. A mold, comprising the drag, the pattern-block provided with a series of individual patterns separated by a series of ridges or ribs and adapted to be set across the drag with its patterns and ribs depending therein, and an imperforate plate-cope adapted to serve as a bottom board to support the sand and, on removal of the pattern, cover the sand and the mold-cavities therein, the said cope being provided over the mold-cavities with non-metallic material; substantially as described.

897,795. BRAKE-SHOE. FREDERICK A. BRAVER, Chattanooga, Tenn. Filed Aug. 28, 1901. Serial No. 72,990. (No model.)

Claim.—1. A brake-shoe having its entire body portion made of hard metal and its wearing-surfaces provided with a series of soft-metal inserts set diagonally across the face of the shoe.

2. A brake-shoe made of hard metal and having a wearing-surface

and a groove, and soft-metal inserts set diagonally in said wearing-surface and transversely in the bottom of said groove.

3. A brake-shoe having a strengthening-rib projecting outward from its inner side, said rib being of greater height in the middle than at the ends.

4. A brake-shoe having a curved inner surface and a strengthening-rib extending from end to end of the shoe on its inner side and having a lesser curvature than the face of the shoe.

5. A brake-shoe having its body made of hard metal and its wearing face provided with a series of soft-metal inserts, and a strengthening-rib extending from end to end of the shoe on its inner side and being higher in the middle than at ends.

697,796. BOTTLE-WASHING MACHINE. HENRY S. BREWSTER, Baltimore, Md., assignor of one-half to William F. Seim, Baltimore, Md. Filed Aug. 27, 1901. Serial No. 73,486. (No model.)

Claim.—1. In a bottle-washing machine the combination with a hollow standard and water-supply pipe, of a revoluble wheel comprising a hollow hub, a ring connected to the hub by hollow spokes, said hub having communication with the hollow standard, a series of vertically-disposed spindles supported upon said hollow ring, valves for controlling the flow of water to the spindles, bottle-holders supported above said hollow ring, means for revolving said spindles and means for simultaneously cutting off the supply of water to the spindles and releasing the bottles from their holders.

2. In a bottle-washing machine the combination with a standard and the water-supply pipe, of a hollow revoluble wheel mounted upon the standard and having communication therewith and comprising a hollow ring, a hollow hub, and spokes connecting said ring and hub, a plurality of spindles supported upon said wheel, valves for controlling the supply of water to said spindles, bottle-holders supported upon said wheel, and means for simultaneously operating said valves successively as the bottles are released from their holders.

3. In a bottle-washing machine the combination with a hollow standard and a water-supply pipe, of a revoluble wheel comprising a hollow hub, hollow spokes, and a hollow ring, said hub communicating with the upper portion of the hollow standard, a plurality of valve-casings supported upon said hollow ring and communicating therewith, valves within said casings, a hollow spindle secured to each of the valve-casings and communicating therewith, a bottle-holder supported above each valve-casing and means for simultaneously operating the valve and bottle-holder.

4. In a bottle-washing machine the combination with a hollow standard and water-supply pipe, of a revoluble wheel comprising a hollow hub, hollow spokes, and a hollow ring, a series of valve-casings supported by said hollow ring, valves within said casings, a hollow spindle secured to each of said casings and communicating therewith, a gear-pinion on each of said spindles and an internally-gear'd stationary ring with which said pinions intermesh.

5. In a bottle-washing machine the combination with a hollow standard and water-supply pipe, of a revoluble hollow wheel, a plurality of spindles supported upon said wheel, a gear-pinion mounted on each of said spindles, a water-pan supported below the wheel, and an internally-gear'd ring supported upon said pan with which said pinions intermesh.

6. In a bottle-washing machine the combination with a revoluble wheel, of a plurality of hollow spindles supported upon said wheel, means for supplying water to said spindles, and a bottle-holder for each spindle, said holder each comprising a plurality of stationary fingers and a movable finger, and means for tilting said movable finger and simultaneously shutting off or turning on the supply of water to the spindle.

7. In a bottle-washing machine the combination with a hollow standard and a water-supply pipe communicating therewith, of a hollow revoluble wheel communicating with the upper portion of the standard, a series of vertically-disposed hollow spindles supported upon said wheel and means for revolving said spindles, a bottle-holder for each spindle provided with a pivoted finger adapted to engage a bottle and means for simultaneously tilting said pivoted finger and shutting off and turning on the supply of water to the spindle.

8. In a bottle-washing machine the combination with a bottle-holder comprising a plurality of stationary fingers and a pivoted finger formed with a lip to engage the bottom of a bottle, of means for tilting said pivoted finger comprising a trip-lever and a projection with which the trip-lever is adapted to contact.

9. In a bottle-washing machine the combination with a revoluble hollow wheel, of a plurality of valve-casings supported on said wheel, a hollow spindle supported upon each of said casings, a valve within each casing, having an outwardly-projecting stem, a bottle-holder for each spindle having a pivoted finger and means for simultaneously operating the said valve and pivoted finger, comprising a trip-lever fulcrumed upon said valve-stem and having an inclined arm and a projection against which said trip-lever is adapted to contact.

10. In a bottle-washing machine the combination with a hollow standard and water-supply pipe communicating therewith, of a pan supported by said standard, an internally-gear'd ring supported upon said pan, a hollow revoluble wheel having communication with the upper portion of the standard, a series of valve-casings mounted upon the wheel, valves within said casings, each having an upwardly-projecting stem, a hollow spindle secured to the upper end of each of said casings, a bottle-holder for each spindle, comprising a plurality of rigid fingers and a pivoted finger formed with a lip to engage the bottom of a bottle, a spring bearing upon said pivoted finger, and means for simultaneously operating said valve and pivoted finger comprising a trip-lever, projections on said pan and an angle-lever pivoted to the under side of the wheel.

11. In a bottle-washing machine the combination with a hollow standard and water-supply pipe, of a revoluble hollow wheel, a stationary pan below said wheel, an internally-gear'd ring having a break or opening at the front of the machine, a plurality of spindles supported by said wheel, and a gear-pinion mounted on each of said spindles, and intermeshing with said internally-gear'd ring.

697,797. BOTTLE-WASHER MACHINERY. HENRY S. BREWSTER, Baltimore, Md., assignor of one-half to William Seim, Baltimore, Md. Filed Sept. 12, 1901. Serial No. 74,905. (No model.)

Claim.—1. In a bottle-washer, the combination with a water-box, and a hollow rotary spindle, of a brush-holder having upwardly-extending arms, brushes removably secured to said arms, and perforated pipes

arranged adjacent to said brushes and communicating with the hollow spindle.

2. In a bottle-washer, the combination with a water-box, of a plurality of hollow spindles revolvably supported by said water-box, brush-holders carried by said spindles, and each comprising a disk having an annular water-chamber communicating with the spindle, upwardly-projecting arms to support the brushes and perforated pipes communicating with the water-chamber of the disk.

3. In a bottle-washer, the combination with a water-box and hollow rotary spindles supported thereby, of gearing connecting said spindles in pairs and causing the members of each pair to revolve in opposite directions, and brush-holders carried by said spindles.

4. In a bottle-washer, the combination with a water-box and hollow rotary spindles supported thereby, of brush-holders supported upon the spindles, brushes removably secured thereto, and yielding devices for supporting the bottles upon the brush-holders.

5. In a bottle-washer, the combination with a water-box, of hollow spindles revolvably supported thereby, brush-holders carried by said spindles, each comprising a disk having an annular water-chamber, parallel arms, and perforated pipes communicating with the spindle, and bottle-supporting devices consisting of a rod extending through the spindle, a yielding disk loosely supported on the upper end of said rod, and a plate supported above the spindle, and provided with depending clamping-springs.

697,798. NON-REFILLABLE BOTTLE. ALFRED J. BRONKH, Prospect Park, Pa., assignor of one-half to George L. Husband, Philadelphia, Pa. Filed Jan. 23, 1902. Serial No. 93,900. (No model.)

Claim.—1. In combination with the bottle having the internal shoulder or offset, the stopper having one or more laterally expandible and contractible arms at its inner end adapted to engage said shoulder, and having at its outer end the enlargement whose base is adapted to rest upon the top portion of the neck of the bottle, which enlargement is provided with two or more communicating ducts extending from a point in the interior of the latter toward the base thereof, and the longitudinal passage-way communicating with said ducts and with the interior of the bottle, together with means for preventing the escape of the contents of the bottle between the body of the stopper and the neck of the bottle, substantially as and for the purpose set forth.

2. In a stopper for bottles of the character described, the combination of one or more laterally contractible and expandible arms on one end of the stopper, an enlargement on the other end thereof whose base is adapted to rest on the neck of the bottle, two or more communicating ducts extending from a point in the interior of said enlargement toward the base thereof, and a longitudinal passage-way in the stopper communicating with said ducts, together with the packing around the portion of the stopper between said arms and said enlargement, substantially as and for the purpose set forth.

3. In combination with the bottle having the internal shoulder or offset, the stopper having one or more laterally contractible and expandible arms on its inner end adapted to engage said shoulder, and having at its outer end the enlargement whose base is adapted to rest upon the top of the neck of the bottle, and having also the communicating ducts extending from a point in the interior of said enlargement toward the base thereof, the longitudinal passage-way leading from said ducts to the interior of the bottle and the packing encircling the body portion of the stopper; together with the cap for preventing the escape of the contents of the bottle, substantially as and for the purpose set forth.

4. In a stopper for bottles of the character described, the combination of one or more laterally contractible and expandible arms on one end of the stopper, an enlargement on the other end thereof adapted to rest upon the top of the neck of the bottle, two or more communicating ducts extending from a point in the interior of said enlargement toward the base thereof, a longitudinal passage-way of the stopper communicating with said ducts, a suitable packing encircling the body portion of the stopper, together with the longitudinal grooves or channels of the said enlargement communicating with said ducts respectively substantially as and for the purpose set forth.

5. In a stopper for bottles of the character recited, the combination of the said contractible and expandible backwardly-projecting and tapering arms on one end of the stopper, the enlargement on the other end thereof, the ducts extending backwardly and outwardly from a point in the interior of said enlargement where they communicate, the longitudinal passage-way leading from the said ducts where they communicate,

and the packing around the body portion of the stopper, substantially as and for the purpose set forth.

6. In combination with the bottle having the internal shoulder or offset, and the depression in the top of the neck thereof, the stopper having one or more laterally expandible and contractible arms at its inner end adapted to engage said shoulder, and having at its outer end the enlargement whose base portion is adapted to rest in the said depression of the bottle-neck, which enlargement is provided with two or more communicating ducts extending from a point in the interior of the latter to the base thereof, the longitudinal passage-way leading from said ducts to the interior of the bottle and the packing or the like for preventing the escape of the contents of the bottle between the body of the stopper and the neck of the bottle, substantially as and for the purpose described.

697,799. KEYBOARD FOR VIOLIN. GEORGE F. BUCHANAN, Albany, Pa. Filed May 21, 1901. Serial No. 92,907. (No model.)

Claim.—1. In a device of the character described, a keyboard having a series of longitudinal openings formed therein, keys operating in said openings, springs carried by said keys, means carried by the springs for securing said keys to the under face of said keyboard, and a yoke for securing said keyboard to the violin, substantially as described.

2. In a device of the character described, a keyboard having openings formed therein, keys operating in said openings, a pair of springs secured to each of said keys, keys carried by the said springs, and means for securing said keys to the keyboard, substantially as described.

3. In a device of the character described, a keyboard having longitudinal openings formed therein, keys operating in said openings, springs secured one to each side of each of said keys, keys carried by said springs and adapted to engage the keyboard, and means securing the keyboard to the violin, substantially as described.

697,800. VEHICLE RUNNING-GEAR. CHARLES F. BROWN, Kansas, Mo. Filed Sept. 7, 1902. Serial No. 93,206. (No model.)

Claim.—1. In a running-gear for a vehicle, the combination of the front and rear head-blocks; a rigid shaft connecting the same; circles secured to the under side of said front and rear head-blocks, the front circle having its center to the rear of the front head-block and the rear circle having its center to the front of the rear head-block; ball-runs grooved into the under side of said circles; the front axle with a suitable circle clipped to the same, corresponding to the circle on the front head-block, the same projecting into the groove of the circle above and being provided with a suitable ball-run; a ball extending down through the shaft and through a bracket on the front axle at the center of the said bearing-circle; an arm D secured to the said ball and the under circle and extending rearwardly; and a pivoted lever F with cap F' carried on the rear end of said arm; a circle carried by the rear axle and fitting into the circle on the said rear head-block being overlapped thereby; an arm E terminating in a round journal portion E' at its forward end, fitting within the

sleeve F and a vertical bolt K extending down through the plate carried by the rear head-block through a bracket on said rear axle and the rear end E' of the arm E, retaining the same securely together, all coacting for the purpose specified.

2. In a running-gear for a vehicle, the combination of the front and rear head-blocks; a rigid reach connecting the same; circles secured to the under sides of said front and rear head-blocks, the front circle having its center to the rear of the front head-block and the rear circle having its center to the front of the rear head-block; ball-races grooved into the under sides of said circles; the front axle with a suitable circle clipped to the same corresponding to the circle on the front head-block, the same projecting into the groove of the circle above and being provided with a suitable ball-race; a belt extending down through the reach and through a bracket on the front axle at the center of the said bearing-circle; an arm D secured to said belt and the under circle and extending rearwardly; and a pivoted sleeve F carried on the rear end of said arm; a circle carried by the rear axle and fitting into the circle on the said rear head-block being overlapped thereby; an arm E terminating in a round journal portion E' at its forward end, fitting within the sleeve F and a vertical bolt K extending down through the plate carried by the rear head-block through a bracket on said rear axle and the rear end E' of the arm E, retaining the same securely together, all coacting for the purpose specified.

3. In a running gear for vehicles, the combination of the front and rear head-blocks; the axle pivoted beneath the same carrying arms extending toward each other, one of which arms has a sleeve F having a cap F' pivoted thereto; and a bolt on the opposite arm extending into the sleeve to afford a sliding and swinging connection between the parts, for the purpose specified.

4. In a fifth-wheel or coupling for a vehicle, the combination with the head-block B; the reach G; the complete circle B' secured to the under side thereof by suitable clips and with a circular ball-race in a groove on its under side, said circle being located with its center to the rear of the axle; the lower circle B'' being narrowed at the top with a ball-race therein, secured by suitable clips to the axle; a bar C secured to the axle having the brackets C' projecting rearwardly therefrom; retaining-bolt H extending through the reach G and through the bracket C' carried by the axle; and yokes, A, A', A'' with extensions B'', B'', fitting in a groove on the under side of the lower circle B'', all coacting substantially as described for the purpose specified.

5. In a fifth-wheel or coupling for a vehicle, the combination with the head-block B; the reach G; the complete circle B' secured to the under side thereof by suitable clips and with a circular ball-race in a groove on its under side, said circle being located with its center to the rear of the axle; the lower circle B'' being narrowed at the top with a ball-race therein, secured by suitable clips to the axle; a bar C secured to the axle having the brackets C' projecting rearwardly therefrom; retaining-bolt H extending through the reach G and through the bracket C' carried by the axle, all coacting substantially as described for the purpose specified.

6. In a fifth-wheel or coupling for vehicles, the combination of a head-block; a reach; an upper circle having a cone-shaped groove in its under surface, the bottom of said groove being circular in cross-section, secured beneath the said reach; an axle; an under circle, the sides of the upper portion of which are made to closely fit the sides of the groove in the said upper circle to form a bearing therewith, and also provided with a ball-race in its upper edge, secured to said axle, for the purpose specified.

7. In a fifth-wheel or coupling for vehicles, the combination of a head-block; a reach; and an upper circle having a cone-shaped groove in its under surface, the bottom of said groove being circular in cross-section, secured beneath the said reach; an axle; an under circle, the sides of the upper portion of which are made to closely fit the sides of the groove in the said upper circle to form a bearing therewith, as specified.

8. In a coupling for a vehicle the combination of the reach G; the plate I with a circular ball-race on a groove on its under side with a downwardly-extending post I' with a head-block above; the axle; the plate J secured by the edge to the upper side of said axle, extending under the plate I and provided with a journal-bearing to embrace the post I' and having a ball-race on its upper side toward the periphery and a ball-race

on its lower side toward the center; the nut I'' with a ball-race on its upper side, screw-threaded to engage the post I'; jam-nut I''' for locking the said ball-bearing nut I'' in position; a bar L with a bracket L' secured to the reach A' and a tie-bolt K extending centrally through the bearing-plates and bracket L' to retain the parts pivotally together, for the purpose specified.

9. In a coupling for a vehicle the combination of a reach; the plate I with a circular ball-race on a groove on its under side with a downwardly-extending post I' with a head-block above; the axle; the plate J secured by the edge to the upper side of said axle, extending under the plate I and provided with a journal-bearing to embrace the post I' and having a ball-race on its upper side toward the periphery and a ball-race on its lower side toward the center; the nut I'' with a ball-race on its upper side screw-threaded to engage the post I'; jam-nut I''' for locking the said ball-bearing nut I'' in position, for the purpose specified.

697,801. DIFFERENTIAL GEARING. WILLIAM S. CANNON, Reno Nev. Filed May 27, 1901. Serial No. 98,578. (No model.)

Claim.—1. A differential gear consisting in the combination with a shaft having a series of gears and having a constant speed in one direction, of a second shaft, loose and fixed gears upon the latter and connections between said gears and the first-named shaft whereby the second shaft is given a variable speed in either direction, said connections including a series of pinions having a common axis and said pinions adapted to engage corresponding gears on said first-named shaft.

2. The combination with a revoluble shaft of a plurality of gears upon one end of said shaft, corresponding pinions engaging said gears, the shafts of said pinions revoluble one within and independently of the other, a shaft in line with and having an axis common to said pinion-shafts, and a clutch mechanism on said aligned shaft adapted to engage with one or the other of said pinion-shafts whereby said aligned shaft is given the same movement as the said engaged pinion-shaft.

3. The combination with a revoluble shaft of a plurality of gears on said shaft, a corresponding number of pinions engaging said gears, said pinions having their shafts revoluble one within and independently of the other, pulleys upon each of said shafts, a shaft in line with said pinion-shafts and having a common axis therewith, a clutch mechanism upon said aligned shaft including a fixed sleeve thereon a collar slidable lengthwise of and revoluble with said sleeve, knee-levers and contractible chucks and means whereby said chucks are made to engage one or the other of said pulleys.

4. The combination with a revoluble shaft, of a plurality of gears upon one end thereof, pinions meshing with said gears, the shafts of said pinions revoluble one within the other, pulleys upon said shafts, said pulleys adjacent to each other and of equal diameter, another shaft, a sleeve fixed on said shaft, a collar slidable on and revoluble with said sleeve, and clamps by which one or the other of said pulleys may be engaged when said collar is moved upon the sleeve, and means by which said slidable movement is effected.

5. The combination of a revoluble shaft, gears thereon, pinions mesh-

ing said gears, the shafts of said pinions having a common axis, a shaft carrying a clutch mechanism adapted to connect with the said pinion-shafts, said mechanism comprising a longitudinally-slidable collar, radially-contractionable cheeks carried upon this collar, a second collar slidable lengthwise on the first-named collar, and knee-levers having one member pivoted on the first-named collar and tending to rotate the cheeks when the second collar is moved upon the first collar.

6. The combination of a revoluble shaft, gears thereon, pinions meshing said gears, said pinions having their shafts revoluble one within another, a shaft having a clutch mechanism, said clutch mechanism adapted to connect with said pinion-shafts, said mechanism including two concentric collars slidable longitudinally in relation to each other and to their supporting-shaft, a rod engaging each of said collars, a lever, one of said rods connecting directly with said lever by which its respective collar is operated, and a segmental lever-and-rack device pivoted on said last-named lever and with which the other rod is connected and by which its respective collar is operated.

7. The combination of a shaft revoluble in one direction at constant speed, a second revoluble shaft, a loose pulley on said second shaft, a fixed gear also thereon, gears journaled on said loose pulley and engaging said fixed gear, connection between the first-named shaft with the loose pulley whereby the latter is given a constant relative speed in one direction, and connections of the first-named shaft with the gears carried on the loose pulley whereby the speed of said gears may be varied, and a motion in either direction gives the second-named shaft.

8. A differential gear consisting in combination, of a shaft revoluble at constant speed in one direction, a series of gears thereon, pinions meshing said gears, the shafts of said pinions revoluble one within another, pulleys fixed on each of said pinion-shafts, a shaft continuous with the innermost of said pinion-shafts and independently revoluble therewith, a clutch mechanism on said shaft adapted to engage one or the other of said pulleys whereby the last-named shaft is given a like motion to the pulley, a shaft carrying fixed and loose pulleys, connections between said pulleys and means whereby said loose pulleys are revolved each constantly in one direction.

9. A differential gear consisting in combination of a revoluble shaft, a series of gears thereon, pinions engaging said gears, said pinions having their shafts revoluble one within another, a shaft carrying engaging fixed and loose pulleys, one of said loose pulleys adapted to be revolved constantly at a relative speed with the first-named shaft, and connections of the other loose pulley with one or the other of said pinion-shafts whereby said pulley is given a movement relative to said pinion-shaft.

697,802. ORB-CRUSHER. ALBERT C. CALKINS, Los Angeles, Cal., assignor to Frederick William Braun, Los Angeles, Cal. Filed Mar. 12, 1906. Serial No. 4,374. (No model.)

Claim.—1. A crusher comprising a vibratory jaw which vibrates in an approximately horizontal arc; and a non-vibrating jaw, the lower section of which non-vibrating jaw is formed of a roll; the portion of the vibratory jaw which is contiguous to the roll being formed in a segment of the outer face of a cylinder, substantially as set forth.

2. In a crusher, the combination of a non-vibrating jaw composed of a fixed section and a roll journaled in the frame to constitute the lower section of said jaw; and a vibratory jaw which vibrates in an approximately horizontal arc, provided with a face having the portion contiguous to the roll formed in the segment of the outer face of a cylinder described from the axis of vibration of the vibratory jaw.

3. A crusher comprising a vibratory jaw and a non-vibrating jaw, the lower section of which non-vibrating jaw is formed of a roll which is free to be propelled in the direction of the discharge-outlet by the crushed material; and means to prevent rotation in the opposite direction; the

portion of the vibratory jaw which is contiguous to the roll being formed in a segment of the outer face of a cylinder.

4. In a crusher, the combination of the frame of the crusher provided with vertical guides and with horizontal ways; a non-vibrating jaw comprising a block with extensions to fit in said ways, means for fastening the block in said guides; blocks to move in said horizontal ways; a shaft journaled in said blocks; a roller mounted to turn on said shaft and to form the lower section of the non-vibrating jaw; and means for holding the blocks in the adjusted position.

5. A crusher comprising a frame provided at the top with an open space extending from the front rearward to receive the vibratory and non-vibrating jaws and provided in its side walls with vertical guides and horizontal ways beneath said guides; a vibratory jaw mounted to vibrate in said space; means for vibrating the jaw; a block to form a section of the fixed jaw provided with lateral extensions to fit in said guides; means for fastening the said block in the guides; blocks to slide in said ways; a shaft fastened at its ends to the blocks; a roll mounted to rotate on said shaft; and means for holding the blocks in said ways to bring the roll into position beneath the fixed section of the non-vibrating jaw to form the lower section of the non-vibrating jaw.

6. In a crusher, the combination of a frame provided with an open space extending from the front rearward to receive the vibratory and non-vibrating jaws and provided in its side walls with vertical guides and horizontal ways beneath said guides; a vibratory jaw mounted to vibrate in said space; means for vibrating the jaw; a block to form a section of the fixed jaw provided with lateral extensions to fit in said guides; means for fastening the said block in the guides; blocks to slide in said ways; a shaft fastened at its ends to the blocks; a roll mounted to rotate on said shaft; frame members extending in front of the horizontal ways; and means in said frame and frame members to adjust the blocks in said ways.

7. In a crusher, the combination of the frame; an eccentric shaft mounted in said frame; a vibratory jaw provided with a seat for a face-plate and having at its lower end a lip to retain the face-plate in said seat and being provided at the upper rear side with a socket for a connecting-rod; a wearing face-plate seated in said seat; a connecting-rod mounted on the eccentric of the shaft and socketing in the said socket and provided with an opening rearward of its socket; and a clamp-piece for the top of the body of the vibratory jaw and provided at its front with a lip to extend in front of the face-plate and provided at the rear with a finger to extend through said opening in the connecting-rod to hold the end of the connecting-rod in the socket; and means for fastening the clamp member to the upper end of said body.

697,808. WATER-CLOSET. JOHN CAMPBELL, Denver, Colo. Filed Oct. 11, 1901. Serial No. 75,234. (No model.)

Claim.—1. In a water-closet, the combination with a hinged cover, of a roll on said cover adapted to swing from the hinge center with the cover; a flush-valve located below the surface of the said cover; a lever adapted to open said valve and provided with opposite inclined faces projecting into the path of movement of the said swinging roll; and a descending, self-draining pipe connection from the said valve to the flushing-entrance of the closet-bowl.

2. In a water-closet, the combination, with a flush-valve, of a lever adapted to open said valve; a hinged cover and seat; rolls upon said cover and seat, adapted to swing from their hinge centers; and oppositely-inclined flaps upon the valve-lever, projecting into the path of movement of the rolls of the cover and seat.

3. In a water-closet, the combination, with a pan supported by a rock-shaft and crank, of a hinged cover; a lever pivoted to said cover eccentric to its hinge; a connection from said lever to said rock-shaft crank; and a fulcrum-bearing in position and adapted to engage the said lever as the cover is tipped.

4. In a water-closet, the combination, with a dump-pan supported by a rock-shaft and crank, of a hinged cover; a lever pivoted to the cover eccentric to its hinge; a connection from said lever to said rock-shaft crank; a hinged seat; and a fulcrum secured to said seat pendulous to its hinge, and in position to engage said lever.

5. In a water-closet, the combination, with a dump-pan, of a hinged cover; a lever and connection from said cover to said pan; and a hinged seat having a fulcrum projection located in position and adapted to be swung out of position to engage said lever when said cover and seat are simultaneously tipped.

6. In a water-closet, the combination, with a hinged cover and hinged seat, of a dump-pan; a lever pivoted to said cover and connected with said pan; a fulcrum on said seat in position and adapted to engage said lever; and a flush-valve operatively connected with said cover.

7. In a water-closet, the combination, with a hinged cover and a hinged seat, of a flush-valve and valve-lever having inclined flaps; projections upon said cover and seat in position and adapted to operate said valve by engaging said flaps; and connections from said cover to said pan, adapted to swing the pan in its upper position when the cover is up and the seat is down.

8. In a water-closet, the combination, with a flush-valve and valve-lever, of a hinged cover in operative engagement with said lever; a cover-lever pivoted eccentric to the cover-hinge; a dump-pan connected with the cover-lever; a resilient fulcrum controlled by a hinged seat; and a descending pipe connection from the flush-valve to the entrance of the closet-bowl.

697,804. KEENING DEVICE. LAMARCA H. CAMPBELL, Allen.
Filed Sept. 11, 1901. Serial No. 78,078. (No model.)

Claim.—1. A keener comprising a block, a handle projecting upward therefrom, and a series of fingers projecting from said block and curved downward.

2. A keener comprising a block, a handle projecting from the upper surface thereof, at an angle to said surface, and a wire bent to form a plurality of downwardly-curved loops, the ends of said wire being secured to the block.

3. A keener comprising a block and handle, said block having transverse horizontal openings, and a resilient wire bent to form downwardly-curved loops curving as fingers, and having their ends inserted in said openings and secured therein.

697,805. HORSE-DETACHER. HOWARD GASKIN, Vandergrift, Pa.
Filed Feb. 5, 1902. Serial No. 98,600. (No model.)

Claim.—1. In a horse-detacher, the combination with the brake-rod carrying brake-shoes, a longitudinally-disposed rod connected at its rear end to the said brake-rod, means carried by the shaft of the vehicle for engagement with the harness, and connected to the forward end of the said longitudinally-disposed rod, and a lever pivoted to the said last-mentioned rod for operating the same.

2. In a horse-detacher, the combination with the shaft of the vehicle, of levers pivoted to the shaft, rods connected to said levers for engagement with the traces and breeching-strap of the harness, a brake-rod carrying brake-shoes, a longitudinally-disposed rod operatively connected to the said levers and brake-rod, and a lever pivoted to the wagon-body and having its lower end pivotedly connected with the said longitudinally-disposed rod.

3. In a horse-detacher, the combination with the shaft of the vehicle, of bell-crank levers pivotedly mounted thereon and spaced apart, rods connected to the outer ends of said bell-crank levers, levers pivotedly secured to the vehicle-shafts for engagement with the traces and breeching-strap of the harness, and in engagement with the said rods, a brake-rod carrying brake-shoes, and means for simultaneously operating the said brake-shoes and bell-crank levers.

4. In a horse-detacher the combination with the shaft of the vehicle, of levers having hooked upper ends, said levers pivotedly secured to said shaft, a brake-rod carrying brake-shoes, and means for simultaneously operating the said brake-shoes and said levers.

5. In a horse-detacher, the combination with the shaft of the vehicle, of levers having hooked upper ends, said levers pivotedly secured to said shaft, bell-crank levers pivotedly mounted upon the shaft, rods connected to the first-mentioned levers and the said bell-crank levers, a brake-rod, a longitudinally-disposed rod connected at its rear end to the said brake-rod, rods connected to the forward end of the said longitudinally-disposed rod and the said bell-crank levers, and means for operating said longitudinally-disposed rod.

697,806. FOLDING CRATE. BARBARA J. CANTRELL, Ocala, Fla.
Filed Mar. 30, 1900. Serial No. 9,678. (No model.)

Claim.—A folding crate comprising a top, bottom, and end sections hinged together; a deck or partition hinged to said end sections and cut away at its corners; and sides hinged respectively to the top and bottom sections, the end rails of which fit the cut-out corners of the deck; and longitudinal battens arranged centrally of the sides and fitting under the side edges of the deck.

697,807. CARBURIZER. CHARLES I. CHANTON, St. Louis, Mo.
Filed June 20, 1901. Serial No. 98,508. (No model.)

Claim.—1. A carburizer having a generator-casing containing loose material, a hydrocarbon-liquid supply for the said casing and having its inlet above the said material, to completely submerge the latter on filling the casing with the hydrocarbon liquid to a desired level, means for maintaining the liquid at the desired level above said loose material, and an air-supply discharging into the said loose material below the top thereof, to divide the air into small parts which, in rising, pass through the hydrocarbon liquid into the upper portion of the casing, as set forth.

2. A carburizer having a generator-casing containing loose material, a hydrocarbon-liquid supply for the said casing and having its inlet above the said material, to submerge the latter on filling the casing with the hydrocarbon liquid to a desired level, a valve controlling the admission of the hydrocarbon liquid to the casing, a float arranged in the casing above the loose material and connected with the said valve, and an air-supply discharging into the said loose material below the top thereof, to divide the air into small parts which, in rising, pass through the hydrocarbon liquid into the upper portion of the casing, the said air-supply having a plurality of valved discharge-pipes opening into the loose material one above the other, as set forth.

3. A carburizer having a generator-casing containing loose material, a hydrocarbon-liquid supply for the said casing and having its inlet above the said material, to submerge the latter on filling the casing with the hydrocarbon liquid to a desired level, an air-supply discharging into the said loose material below the top thereof, to divide the air into small parts which, in rising, pass through the hydrocarbon liquid into the upper portion of the casing, and a circulating connection for connecting the hydro-

carbon liquid in the casing with the lower portion of the loose material, to allow the liquid to flow by gravity into the loose material at the lower part thereof, as set forth.

4. A carburetor having a generator-casing containing loose material, a hydrocarbon-liquid supply for the said casing and having its inlet above the said material, to submerge the latter on filling the casing with the hydrocarbon liquid to a desired level, an air-supply discharging into the said loose material below the top thereof, to divide the air into small parts which, in rising, pass through the hydrocarbon liquid into the upper portion of the casing, an overflow above the predetermined level of the liquid, and a closed safety-tank connected with the said overflow, as set forth.

5. A carburetor having a generator-casing containing loose material, a hydrocarbon-liquid supply for the said casing and having its inlet above the said material, to submerge the latter on filling the casing with the hydrocarbon liquid to a desired level, an air-supply discharging into the said loose material below the top thereof, to divide the air into small parts which, in rising, pass through the hydrocarbon liquid into the upper portion of the casing, and an air-pump for the said air-supply having its discharge-pipe rising above the generator-casing, the discharge-pipe containing a check-valve, as set forth.

6. A carburetor, comprising a casing containing loose material, and having an outlet at its top, a reservoir for hydrocarbon liquid provided with a discharge-pipe opening into the casing above the loose material, an air-pump having a U-shaped discharge-pipe rising above the top of the casing, a series of pipes connected with one leg of said discharge-pipe and extending into the casing, the said pipes opening into the loose material one above the other, as set forth.

7. A carburetor, comprising a casing containing loose material, a hydrocarbon-liquid supply for the said casing and having its inlet above the loose material to submerge the latter, an air-supply discharging into the loose material below the top thereof, a pipe extending from the hydrocarbon liquid in the casing to the lower portion of the loose material, an overflow-pipe leading from the casing above the predetermined level of the liquid, and a tank connected with the said overflow-pipe, as set forth.

697,808. FASTENING DEVICE FOR GARMENT-SUPPORTERS. JAMES P. COLLIER, Paris, France. Filed Sept. 28, 1900. Serial No. 121,888. (No model.)

Claim.—The combination of a perforated plate and a tongue projecting into said perforation, of a button, a circumferential groove therein and a cut-away portion in one of the walls of said groove to admit entrance of the tongue into the same, substantially as set forth.

697,808.

697,809. WEARING-APPAREL. ISA W. COLLIER, Kilmarnock, Mo. Filed July 23, 1901. Serial No. 68,800. (No model.)

Claim.—1. A device of the character described, formed of moisture-proof material shaped to fit the part to which it is applied, the opposite ends thereof being provided with buttonholes, and the exposed edge of the device having hooks which are elastically connected thereto.

2. A device of the character described, formed of moisture-proof material and shaped to fit the part to which it is to be applied, the opposite ends thereof being provided with buttonholes, the exposed edge of the material being rolled over upon the outer side thereof, and hooks elastically connected to the opposite edge of the device.

3. A device of the character described, having its opposite ends provided with corresponding buttonholes, its exposed edge being rolled over upon the outer side thereof, and fastenings elastically connected to the opposite edge of the device.

697,810. ELECTRIC FURNACE. WILLIAM R. COLLEY, New York, N. Y., assignor to Electric Furnace Company, a Corporation of New York. Filed Dec. 5, 1901. Serial No. 84,704. (No model.)

Claim.—1. An electric furnace having its body portion made of refractory non-conducting material and formed with a main inner chamber, a neck at the bottom of said inner chamber, a hearth below the neck, a heating zone forming substantially the wall of the neck and made up of a series of plates or parts adapted to be heated to incandescence by the passage of an electric current through them, and a second heating zone in the hearth formed also of plates or parts which are adapted to be substantially flush with the furnace-wall and incandescent under the influence of a strong electric current.

2. The herein-described electric furnace, comprising a body made of refractory non-conducting material and having its inner portion closed to exclude the ingress of air and provided in its walls with a plurality of heating zones arranged on different horizontal planes, the inner parts of the heating zones lying substantially flush with the furnace-wall and the said zones being made of material of low electrical conductivity adapted to glow incandescent under the influence of an electric current.

3. An electric furnace, comprising a body portion formed of refractory non-conducting material and closed to prevent the ingress of air while the furnace is in operation, the said body being reduced interiorly to form a comparatively small neck with a hearth below the neck, the hearth, neck and chamber of the body forming one continuous incandescent, and a heating zone or bulb forming the wall of the neck, said bulb or zone being made of material of low electrical conductivity adapted to glow incandescent on the passage of an electric current through it.

697,811. GARMENT-SUPPORTING APPLIANCE. JOHN P. SHAW, New York, N. Y. Filed Sept. 2, 1901. Serial No. 74,100. (No model.)

Claim.—As an improvement in garment-supporters, the combination with the band B, and means thereon for supporting it on the lower end of a waist, of the plate C, having slots c' c' for the passage of the band, and a y-shaped extension d', at the upper end, and a cam-snap pivoted to the free end of the extension d', said snap having its gripping edge provided with prongs adapted to engage the slots c' c', in the plate C, for the purpose described.

697,812. FLEXIBLE-GRASP COLLAR OR CUFF BUTT. JAMES H. CHAM, Indianapolis, Ind. Filed July 1, 1901. Serial No. 68,005. (No model.)

Claim.—In a flexible button, the combination of the hollow yielding band, the unyielding one in said hollow band extending nearly to the edge thereof, the hollow yielding band, the unyielding one in said hollow band extending nearly to the edge thereof, and the band attached to said band and to said one, substantially as shown.

697,813. HEATING SYSTEM. JAMES H. CHAM, Madison, N. H. Filed Nov. 21, 1900. Serial No. 87,300. (No model.)

Claim.—1. In a heating apparatus of the character described, the combination with a radiator comprising a series of vertically-disposed sections, a heater provided with a water-jacket, go and return pipes communicating with the water-jacket and with the adjacent end of the radiator at the top and bottom thereof, an expansion-tank located above the radiator and provided with an ingo-pipe communicating with an inter-

mediate section of the radiator and extending nearly to the top of the tank, an open-pipe communicating with the hot section of the radiator at the end thereof furthest from the heater and communicating with the bottom of the expansion-tank at the end thereof opposite the ingo-pipe, and a safety-valve on said tank designed to permit the escape of steam to prevent excessive steam-pressure in the radiator.

2. In a heating system, the combination with a heater comprising a water-jacket, a combustion-chamber located thereby, an air-box located below the water-jacket and having its upper edge secured directly to the outer wall thereof, a heat-dome located above the jacket and having its lower edge fitted closely around and secured directly to the outer wall thereof, and a dampener shell enclosing the water-jacket in spaced relation thereto, the ends of said shell being extended above and below the water-jacket in order to insure the joints between said jacket and the air-box and dome respectively, of go and return pipes passed through and constituting exclusive supports for the shell and communicating with the water-jacket adjacent to the upper and lower ends thereof to constitute a circulatory system, one or more radiators incorporated in said system, an expansion-chamber in communication with the system of the pipes most remote from the heater, and means for automatically relieving the pressure of the expansion-chamber.

697,814. SHOT-MAKING MACHINE. JAMES L. GORMAN, Dunedin, New Zealand. Filed July 20, 1901. Serial No. 75,140. (No model.)

Claim.—In a machine for manufacturing shot, a disk having circumferential peripheral grooves and mounted upon a rotatable shaft, a band constructed of yielding material including one half of the periphery of said disk and having its ends extended to insure the upper and lower portions of the other half of the grooved periphery of said disk, said band having its inner face provided with grooves registering with the peripheral grooves of the disk, said grooves adapted to receive the material for rolling it into shot, means suitably connected to the ends of said band for adjusting the width of the space between the band and disk when desired, a hopper for the material integral with the said band and communicating with the grooves thereof and the grooves of the disk, and segment-shaped scrapers connected to the upper end of said band and extending toward the lower end thereof and engaging in the grooves for removing the shot therefrom, substantially as herein shown and described.

697,815. MEANS FOR VENTILATING BUILDINGS. THOMAS BARRINGTON, South Melbourne, Victoria, Australia. Filed Oct. 21, 1901. Serial No. 75,620. (No model.)

Claim.—1. Improved means for ventilating buildings comprising blocks (such as A) of brick or other material having part of their upper surface inclined and fitted with projections (as B) at intervals in combination with rolled-iron or other bars (as C) having their adjacent surfaces formed with projections (as D) the whole being constructed and arranged substantially as set forth for the purpose specified and illustrated in the accompanying drawings.

2. In means for ventilating buildings, oblong blocks of brick or other material having part of their upper surface inclined and formed with projections (as D) along one side, substantially as and for the purpose specified, and as illustrated in the accompanying drawings.

697,816. GOLF-BALL. CHARLES DAVIS, U.S. Navy. Filed Sept. 27, 1901. Serial No. 73,705. (No model.)

Claim.—1. A golf-ball, comprising a hollow spherical shell composed of a nitrocellulose compound and an elastic coating exterior to said shell and provided on its outer surface with a plurality of projections, substantially as described.

2. A golf-ball, comprising a hollow central shell of a nitrocellulose compound, an outer envelope of gutta-percha provided with a plurality of projections thereon, and an intermediate layer of elastic material not integral with either the inner shell or the gutta-percha coating, substantially as described.

3. A golf-ball, comprising a hollow central shell of a nitrocellulose compound, an outer envelope of gutta-percha provided with a plurality of projections thereon, and an intermediate layer of rubber not integral with either the inner shell or the gutta-percha coating, substantially as described.

4. A golf-ball, provided with a plurality of projections thereon, and comprising a hollow spherical shell of elastic material, and a distinct elastic coating thereon, with air-pockets between the shell and coating, substantially as described.

5. A golf-ball, provided with a plurality of projections thereon, and comprising a hollow central shell of highly-elastic material, an outer envelope of gutta-percha, and an intermediate layer of elastic material, with air-pockets provided between the outer envelope and the intermediate elastic material, the said intermediate layer being not integral with either the inner shell or the exterior coating, substantially as described.

6. A golf-ball, provided with a plurality of projections thereon, and comprising a hollow central shell of highly-elastic material, an outer envelope of gutta-percha, and an intermediate layer of elastic rubber, with air-pockets between said outer envelope and said rubber layer, the said intermediate layer being not integral with either the inner shell or the outer coating, substantially as described.

697,817. DEVICE FOR ELECTRICALLY CONNECTING RAILS. GERHARD DUNHAM, Winsted, Conn. Filed Jan. 11, 1902. Reissued Oct. 15, 1901. Serial No. 73,706. (No model.)

Claim.—1. A new and improved electrical conductor for connecting rails, and comprising a binder formed hollow with one end normally closed and fitted, said binder being adapted to be wedged home in suitable holes formed in the said rails offering an increased surface of contact for conducting the current and insuring permanency of the said binder in position, substantially as described.

2. In a new and improved binder for electrically conducting rails for conducting a current the combination of a cylindrical hollow body adapted to pass through holes provided in said rails, an annular flange on one end of said binder-body, a slotted normally closed end in said other end and a bolt adapted to be driven into said binder expanding the same and wedging it firmly and permanently in place, substantially as described.

3. In a new and improved binder for electrically conducting rails for conducting a current, the combination of a hollow cylindrical, slotted body, a neck formed on each end thereof, a flange on one end of said binder, a connecting slotted web, one thereon and bolts adapted to be driven into said binder and wedge the same permanently into place offering a large contact-surface for the current, substantially as described.

697,818. TANK FOR STORING ABRATED LIQUIDS UNDER PRESSURE. GEORGE S. DE LAET, New York, N. Y. Filed Oct. 12, 1901. Serial No. 73,682. (No model.)

Claim.—1. In a tank for storing abraded liquids, a joint for sections or parts of said tank, comprising a collar-tight recess formed in one of the parts to be united, the inner wall of which presents a smooth surface and tapered edge, rivets extending through the inner and outer walls of said recess and counterbored in the inner wall, and bayonet-joint slots formed on the other part which receives the rivets, as said part enters the recess and engages with them as the parts are relatively turned; the parts being soldered together to prevent turning in a manner to disengage the bayonet-joint.

2. In a tank for storing abraded liquids, the combination of a body portion having bayonet-joint slots formed near its annular edge and a bottom formed with a collar-tight recess constructed to receive said body portion, and rivets extending through the walls of said recess, the inner wall presenting a smooth interior face with outwardly-tapered annular edge; the parts being interlocked and soldered to prevent unscrewing.

3. In a metal tank, the combination of a body portion having bayonet-joint slots, a bottom having a lip surrounding the body portion, an inner ring covering the joint between the body portion and bottom, spaced apart from the lip to provide a recess to receive the body portion and rivets secured in the inner ring, and in the lip, and passing through the bayonet-joint slots.

4. In a metal tank, the combination of a body portion having bayonet-joint slots, a bottom having a lip surrounding the body portion, an inner ring covering the joint between the body portion and bottom, forming with said lip a recess to receive said body portion and having inclined edges to avoid making shoulders with said body portion or the bottom, and rivets having their outer ends secured in the lip, and with their inner ends flush with the inner face of the inner ring and passing through the bayonet-joint slots.

5. A joint for metal tanks, comprising bayonet-joint slots in the body portion, a cap having a lip surrounding the body portion, an inner ring for covering the joint between the body portion and cap, fixed within the cap with a space between it and the lip to receive the body portion, and having a collar-tight connection with the cap, and rivets secured in said ring and in the lip and passing through the bayonet-joint slots.

6. A joint for metal tanks, comprising the body portion formed with bayonet-joint slots, a cap having a lip surrounding the body portion, a ring for covering the joint between the body portion and cap, fixed within the cap with a space between it and the lip to receive the body portion, and soldered at its lower edge to the cap to form a collar-tight closure at the bottom of said body-portion space and rivets fixed at their ends in the ring and lip and passing through the bayonet-joint slots.

697,819. LATCH ATTACHMENT. WILLIAM H. DICK, New York, N. Y. Filed Dec. 26, 1901. Serial No. 67,682. (No model.)

Claim.—1. A turn-bolt attachment, comprising a body-plate adapted to be fastened to the inner turn-bolt and to project therefrom, a spring-latch carried by the body-plate and normally projecting from the face thereof in the path of the turn-bolt-rod or lever, a stop-pin carried by the said body-plate at one side of the latch, and means for holding the latch in inactive position, as set forth.

2. A latch attachment, comprising a body-plate, a sleeve fitted thereto and projecting from one face thereof, a spring-latch carried in the sleeve and biased on its outer side, a head or finger-piece on the stem of the latch at the projecting end of the sleeve, a pin projecting from the head or finger-piece of the latch, and adapted to engage the end of the sleeve to hold the latch inactive, the said pin normally engaging an opening in the said sleeve, and a stop-pin projecting from the face of the body-plate at the inner side of the latch.

3. A latch attachment, comprising a body-plate adapted to be fastened to the latch, a sleeve secured in the body-plate and flush with the upper surface thereof, the sleeve projecting below the lower face of the plate, a spring-latch carried in the sleeve and having a stem extending through a contracted opening in the lower part of the sleeve, a head or finger-piece on the lower end of the stem, and adapted to normally engage the lower end of the sleeve, an oppositely-extending pin on said head and adapted to engage an opening in the lower end of the sleeve, the head or finger-piece of the latch, when drawn down to retract the latch being capable of being turned to move the pin out of registry with said opening to hold the latch retracted, and a stop-pin projecting upward from the plate at one side of the latch as set forth.

697,820. CAR-DOOR AND GRAIN-DOOR OPERATOR. WILLIAM H. DUNHAM and JOHN A. WILSON, Cumberland, Md. Filed Sept. 26, 1901. Serial No. 73,772. (No model.)

Claim.—1. In combination with a car-door, a grain-door arranged to the rear thereof, a handle carried by the car-door for moving said grain-door thereto, longitudinal ribs carried by said grain-door, a cross-bar secured transversely to said ribs, levers having a locking-pin, said levers adapted to extend through said ribs, engage said cross-bar and engage the car-door frame, substantially as described.

2. In combination with a car-door, a grain-door arranged to the rear thereof, a handle carried by the said car-door for engagement with said grain-door, longitudinal ribs carried by the grain-door for engagement with the car-door frame, a cross-bar carried by the grain-door, levers having a downwardly-extending locking-pin, chains connecting said levers to said cross-bar, said levers adapted to pass through the longitudinal ribs and engage the car-door frame with said locking-pin engaging through the cross-bar, and a bar carried by the car-door and connected to the cross-bar, substantially as described.

697,821. MUSH-ROLL. LOUIS R. DUNHAM, Hattisburg, N. Y. Filed July 22, 1901. Serial No. 68,222. (No model.)

Claim.—1. A mush-roll having its perforations gradually increasing in length to compensate for the increasing diameter of the take-up roll.

2. A mush-roll having provision for the automatic compensation of the increased size of the take-up roll.

3. A mush-roll or roll having gradually-increasing length of space occupied by members, perforations and bridges between perforations from the beginning to the end, whereby the increasing linear speed of the mush-roll and consequently increasing speed of the mush due to the windings of the sheet on the take-up roll are compensated for.

4. A perforated mush-roll having its perforations regulated as to length according to the diameter of the roll.

5. A perforated mush-roll or roll having provision for keeping the time of the mush constant as the feed becomes faster due to the increasing diameter of the take-up roll.

6. A perforated mush-roll or roll having provision allowing for a gradual increase in its linear speed as the take-up roll increases in size without increasing the speed or "tempo" of the mush.

7. A perforated mush-roll or roll having its perforations and bridges between perforations regulated as to length according to the diameter of the roll.

8. A perforated mush-roll or roll for use on instruments provided with means for revolving its take-up roll a certain number of revolutions per unit of time, said perforated sheet or roll being provided with means whereby the increasing linear speed of the mush-roll and consequently increasing tempo of the mush due to the increasing circumference of the take-up roll are compensated for.

697,822. CURTAIN-FIXTURE. ALBERT E. W. DUFFIELD, New-castle, Pa. Filed Aug. 2, 1901. Serial No. 73,684. (No model.)

Claim.—In a curtain-fixture, brackets composed of flat sheet metal having recesses formed in their front edges, springs secured to the top of the window-frame with their lower ends bowed and extending in alignment with said recesses, pulleys mounted between said springs and brackets, a pulley secured to the upper end of one of said brackets, a pulley adjustably mounted on the lower end of said window-frame, a cord secured to one end of the curtain-pole and being passed over both of said first-named pulleys, an endless cord pinned over said pulley carried by the upper end of the bracket and over the pulley secured to the window-frame, the end of said first-named cord being secured to said endless cord.

697,823. SHIRT. SYDNEY J. BELLARD, Dublin, Ireland. Filed Jan. 12, 1902. Serial No. 69,682. (No model.)

Claim.—1. A shirt composed of two side halves, and a yoke or neck-band, said side halves being fastened to said neck-band or yoke in such a manner that they overlap each other at the front and rear.

2. A shirt composed of two side halves, provided with the usual sleeves, and a yoke or neck-band, said side halves being fastened to said yoke or neck-band in such a manner that they overlap each other at the

front and rear and drupe downward, each side half being cut on a long curve from its upper, inner edge to its lower outer edge, so as to produce a bifurcation at the lower part of the shirt.

3. A shirt, composed of two side halves provided with the usual sleeves, and a yoke or neckband, said side halves being fastened to said yoke or neckband in such a manner that they overlap at the front and rear and drupe downward free from each other, one of said side halves being fastened to said yoke or neckband in such a way that it may be detached therefrom for the purpose of putting on or taking off the shirt, and each of said side halves being cut on a long curve from its upper, inner edge to its lower, outer edge so as to produce a bifurcation at the lower portion of the shirt.

697,824. MACHINES FOR SHEARING AND CLIPPING WOOL OR HAIR. WILLIAM H. HYMAN, Sydney, New South Wales, Australia, assignor to Hyman and Bell, Limited, Sheffield, England, a Corporation of England. Filed Apr. 15, 1901. Serial No. 69,493. (No model.)

Claim.—1. In combination for a sheep-shearing apparatus, a rocker-bar and a rocker-tension-spring having cross-head pins and passing through the rocker-bar, said rocker-bar having a U-shaped frame constructed in the top thereof to receive the cross-head pins and means for adjusting the spring, substantially as described.

2. In combination, the rocker-bar, the tension-spring passing through the same and having laterally extending pins resting on the top edges of the rocker-bar, the cutters and the roller-bearing for the rear end of the rocker-bar, said spring having a bearing above and below in the frame, substantially as described.

3. In combination in a sheep-shearing machine, a casing, a rocker-bar, a dust-escape of flexible material and suitable means for securing it to the front end of the casing and rocker-bar, substantially as described.

4. In combination with the cutters, a fork to press said cutters together and fast or points inserted in the lower face of the fork and bearing upon the upper cutter, substantially as described.

697,825. WURMERY MILK-WARMER AND NIGHT-LAMP. JAMES H. FINE, Malone, N. Y. Filed July 27, 1901. Serial No. 69,576. (No model.)

Claim.—1. In a wormery milk-warmer and night-lamp, an outer vessel for liquid, an inverted inner vessel constituting a bottom for said outer vessel and forming therewith a space for the liquid, the adjacent walls of said vessels being cut away on each side of the said space to form an opening, a substantially horizontal tube or casing connecting said walls at the cut-away portions, a ground-glass window in said tube or casing, an electric lamp within the inner vessel having its main light-giving portion opposite the window, and a bottom plug fitted closely and supported frictionally within the lower end of the inner vessel for holding the lamp in position, said plug being fitted with a non-conductor of heat.

2. In a wormery milk-warmer and night-lamp, an outer vessel for liquid, an inverted inner vessel constituting a bottom for the outer vessel and forming therewith a heating-space for the liquid, the adjacent walls of said vessels being cut away on each side of the said space to form an opening, a substantially horizontal tube or casing connecting said walls at the cut-away portions, a bottom plug fitted closely within the lower end of the inner vessel and an electric lamp within the inner vessel, said lamp being supported by the bottom plug and having its main light-giving portion opposite the tube or casing.

3. In a device of the character described, an outer vessel for liquid, an inverted inner vessel constituting a bottom for the outer vessel and forming therewith a heating-space for the liquid, the adjacent walls of said vessels being cut away on each side of the said space to form an opening, a substantially horizontal tube or casing connecting said walls at the cut-away portions, a double-convex ground-glass window in said tube or casing, an electric lamp within said inner vessel for heating the liquid and emitting a light through said window, the main light-giving portion of the lamp being opposite the window, and a bottom plug fitting the mouth of the inner vessel and holding the lamp in position.

4. In a device of the character described, an outer vessel for liquid, a cover for said vessel, an inverted inner vessel constituting a bottom for the outer vessel and forming therewith a heating-space for the liquid, the adjacent walls of said vessel being cut away on each side of the said space to form an opening, a substantially horizontal tube or casing connecting said walls at the cut-away portions, a double-convex ground-glass window in said tube or casing, an electric lamp within said inner vessel for heating the liquid and emitting a light through said window, the main light-giving portion of the lamp being opposite the window, a bottom plug fitting the mouth of the inner vessel and holding the lamp in position, said plug being substantially a non-conductor of heat, means connected with the outer vessel near its top for hanging up the device, and means connected with said outer vessel near its bottom for preventing the same from rocking.

697,826. ELECTRICAL SHEDDING APPARATUS FOR SHEEP. BRADLEY A. FINE, U. S. Navy, assignor to Western Electric Company, a Corporation of Chicago, Ill. Filed Oct. 17, 1900. Serial No. 26,226. (No model.)

Claim.—1. In an electrically-controlled shearing apparatus, the combination with a beam, of an electric motor device and mechanism associated therewith for moving the beam, a hand steering-wheel, and a generator of electricity having an armature or rotor adapted to be turned by said steering-wheel, and connected with the motor device, whereby the beam may be controlled by moving said steering-wheel, substantially as set forth.

2. In an electrically-controlled shearing apparatus, the combination with a beam and an engine for operating the same, of an electric motor device controlling the engine, and a generator of electricity having an ar-

ature or rotor adapted to be turned by hand, said generator being electrically connected with said motor device, whereby the beam may be moved in one side or the other by turning the armature or rotor of the generator in a corresponding direction, substantially as described.

3. In an electrically-controlled shearing apparatus, the combination with a beam and a steering-engine for moving the same, of a reversing-valve for the engine, a polyphase-current induction-motor for moving the reversing-valve and for controlling the engine, a hand steering-wheel, and a generator of polyphase currents geared to said steering-wheel and connected with the said induction-motor, substantially as set forth.

4. In an electrically-controlled shearing apparatus, the combination with a beam and an engine for operating the same, said engine having a reversing-valve, whereby it may be controlled, said valve being adapted to be moved in either direction to cause the engine to run correspondingly, the valve being normally maintained in a central position to keep the engine at rest, of an induction-motor adapted, under the influence of polyphase currents transmitted thereto, to open the valve in one direction or the other, and a generator of polyphase currents connected with said motor, said generator being adapted to be manually operated, whereby the beam may be moved in one side or the other by turning the generator, substantially as described.

5. In an electrically-controlled shearing apparatus, the combination with a beam and a steering-engine adapted to operate the same, said engine having a reversing-valve whereby it may be controlled, said valve being adapted to be moved in either direction to cause the engine to run in one direction or the other, according to the direction of such movement, the valve being normally maintained in a central position to keep the engine at rest, of an electric motor device adapted to move said valve in either direction, according to the character of current supplied to it, and a generator of electricity connected with said motor device and adapted to be operated manually to supply current of suitable character to operate said motor device in either direction, whereby the engine may be caused to move the beam in one side or the other by manually operating the generator in a corresponding manner, substantially as set forth.

697,827. JOINING FLANGES FOR TIE-ROPS. BENJAMIN FLEISS, Schwanau, Germany, assignor of one-half to Franz Engel, doing business under the firm-name of Engel & Green, Bremen, Germany. Filed Nov. 12, 1901. Serial No. 69,690. (No model.)

Claim.—1. In a coupling the combination with joining-flanges on the parts to be coupled shearing against each other, one of said flanges having radial slots, of tappets reversibly moved in said slots and pressing-curves mounted in said tappets in position to engage the other flange, substantially as described.

2. In a coupling the combination with joining-flanges on the parts to be coupled shearing against each other, one of said flanges having radial slots, of tappets reversibly guided in said slots, pressing-curves mounted in said tappets in position to engage the other flange and means for simultaneously moving all said tappets toward and from the center, substantially as described.

3. In a coupling the combination with joining-flanges on the parts to be coupled shearing against each other, one of said flanges having radial slots, of tappets reversibly guided in said slots, pressing-curves mounted in said tappets in position to engage the other flange and means for simultaneously moving all said tappets toward and from the center comprising a disk having a plurality of spiral grooves to receive tappets or projections from the tappets, substantially as described.

697,828. TIE-ROD JOINT. FRANK L. FOWLER, Philadelphia, Pa. Assignor of two-thirds to Theodore A. Royal, Jr., and Harold Kottler, Philadelphia, Pa. Filed July 11, 1901. Serial No. 67,327. (No model.)

Claim.—1. In a tie-rod joint, formed in sections, one of which is secured to a rod and the other carrying the tie-rod wheel, a pin rigidly secured to one section and reversibly connected to the other section whereby one section can turn with respect to the other section, said sections comprising a disk of said section, each spring having one end secured to the section and the other end secured to the other section.

2. In a tie-rod joint formed in sections, a pin rigidly secured to one section, means for reversibly securing said pin to the other section and serving as an axis therefor, pins secured to said sections and springs coiled in opposite directions connected with said sections for holding the parts in normal position.

3. In a tie-rod joint formed in sections, a pin rigidly secured to one section, a head on said pin with a reduced neck connecting the same and forming a recess around said pin, and a bolt seated in said recess and connected with the other section, whereby said pin serves as an axis for said section and connects the same together.

697,829. CONVERTING MOTION. GEORGE H. FRALBY and GEORGE F. HALL, Alma, Mich. Filed Jan. 14, 1902. Serial No. 69,577. (No model.)

Claim.—1. The apparatus for converting motion, substantially as herein described, consisting of the reversing rod, a drum, a cord connected between the drum and the rod whereby the rod as it is depressed will revolve said drum, a spiral drum in connection with said first drum and transmitting therewith, a main shaft-wheel, a gear, a spring

connection between the gear and the ratchet-wheel, pivoted pawl-lever provided with pawls engaging said main ratchet, a cable connecting said lever, a guide for said cable, and cable connections between each of said levers and the second drum all substantially as set forth for the purpose set forth.

2. In an apparatus substantially as described the combination with a main ratchet-wheel and the pawl-lever provided with pawls and operating thereon, of means for operating said lever, a device arranged for operation by the main ratchet-wheel, and a spring connection between said device and the main ratchet-wheel substantially as set forth.

3. The combination of the reciprocating rod, the drum adjacent thereto, the cord connection between the drum and rod whereby the rod may oscillate the drum, a second drum in connection with the first drum, the main ratchet-wheel, the lever having pawls operating upon said ratchet-wheel, and cable connections between said levers and the second drum substantially as set forth.

4. The combination with the main ratchet-wheel of pawls operating upon the said wheel, lever device carrying said pawls, the reciprocating rod, and intermediate devices between said rod and the lever device substantially as set forth.

697,880. APPARATUS FOR MEASURING AND DRAWING LINES. HENRY FRANK, London, England. Filed Aug. 26, 1901. Serial No. 73,334. (No model.)

Claim.—1. In a device of the class described, a vessel having primary and secondary compartments in communication, a conduit communicating with the primary compartment and arranged to communicate with a suitable receptacle, a second conduit, connected with the secondary compartment, and a tube having an end in the primary compartment, and the other end arranged to be connected with said receptacle, and the primary compartment having air-venting means.

2. In a device of the class described, a vessel having communicating primary and secondary compartments, a conduit communicating with the primary compartment and arranged to communicate with a suitable receptacle, a second conduit, communicating with the secondary compartment, and a tube passing through the first conduit and having one end in the primary compartment, said tube being also arranged to communicate with said vessel, and said primary compartment having air-venting means.

3. In a device of the class described, a vessel, an inclined partition dividing said vessel into a plurality of superposed communicating compartments the upper compartment having an air-vent, a conduit connected with the lower compartment, a second conduit connected with the upper compartment, and a drawing-tube having an end in the upper compartment, the opposite end of said tube and the lower end of the second conduit being arranged for communication with a suitable receptacle.

697,881. METHOD OF RECOVERING METALS BY ELECTROLYSIS. HENRY FRANK, London, Canada. Filed Dec. 1, 1901. Serial No. 68,254. (No specimens.)

Claim.—1. The process of recovering metals by electrolysis, which consists in electrolyzing a double salt of ammonium and metals whose hydrides are soluble in ammonium, in presence of a suitable anode and an anode electrolyte (anolyte) containing metals different from the one contained in the cathode electrolyte (catholyte) but free from ammonium.

2. The method of electrolyzing a double salt of ammonium and metals whose hydrides are soluble in ammonium, consisting of electrolyzing a solution of an ammonium double salt containing metal in presence of an anode capable of combining with the acid or halogen radicals contained in the ammonium double salt, and having constituents different from the contents of the catholyte.

3. The method of recovering ammonium from an electrolyte composed of an ammonium double salt, consisting in electrolyzing a solution of an ammonium double salt containing metal in presence of a suitable anode, and an anode capable of binding the acid or halogen radical of the ammonium salt, the cathode and anode being separated by a suitable diaphragm, depositing the metal contained in the solution upon the cathode, and binding the acid or halogen radical to the substance of the anode, keeping the ammonium in solution in the cathode electrolyte.

4. The method of recovering nickel from a nickel-ammonium salt,

consisting in supplying an electrolytic bath with an anode composed of a metal-bearing substance in a concentrated form, covering it with a chemically and electrically inert permeable substance above which suitable cathodes are arranged, supplying the anode with a solution capable of dissolving the metallic salts therefrom, applying the cathode with a solution of the nickel-ammonium salt, subjecting it to an electric current, depositing the nickel upon the cathodes and displacing the metallic solution at the anode by a fresh supply of solvent, keeping the ammonium in solution in the cathode electrolyte.

5. The process of recovering nickel by electrolysis, which consists in supplying a cathode with a solution of nickel-ammonium chloride containing an excess of ammonium, and supplying a suitable anode consisting of different metals with a solution of sodium chloride, separating the two solutions by means of a permeable diaphragm, and by means of an electric current precipitating the nickel in metallic form upon the cathode, and forming at the anode a solution of the chloride of the various metals contained in the anode, substantially as described.

6. The process of recovering nickel by electrolysis, which consists in supplying a cathode with a solution of nickel-ammonium chloride containing an excess of ammonium, and supplying a suitable anode consisting of different metals with a solution of sodium chloride, separating the two solutions by means of a horizontal permeable diaphragm, and by means of an electric current precipitating the nickel in metallic form upon the cathode, forming at the anode a solution of the chloride of the various metals contained in the anode, and displacing the chloride solution from below the diaphragm by addition of fresh sodium-chloride solution.

7. The process of recovering nickel by electrolysis, which consists in supplying a cathode with a solution of nickel-ammonium chloride containing an excess of ammonium, and supplying a suitable anode consisting of different metals with a solution of sodium chloride, separating the two solutions by means of a horizontal permeable diaphragm, and by means of an electric current precipitating the nickel in metallic form upon the cathode, forming at the anode a solution of the chloride of the various metals contained in the anode, displacing the chloride solution from below the diaphragm by addition of fresh sodium-chloride solution, and further electrolyzing the cathode solution until the last trace of nickel has been removed.

8. The process of recovering nickel by electrolysis, which consists in supplying a cathode with a solution of nickel-ammonium chloride containing an excess of ammonium, and supplying a suitable anode consisting of different metals with a solution of sodium chloride, separating the two solutions by means of a horizontal permeable diaphragm, and by means of an electric current precipitating the nickel in metallic form upon the cathode, forming at the anode a solution of the chloride of the various metals contained in the anode, displacing the chloride solution from below the diaphragm by addition of fresh sodium-chloride solution, and further electrolyzing the cathode solution until the last trace of nickel has been removed from the cathode electrolyte, and adding the remaining solution of free ammonium for the production of fresh nickel-ammonium chloride.

697,882. ELECTRIC TRANSMISSION OF POWER. ROBERT H. FRANK, Toronto, E. T., assignor to the Niagara Company, New York, N. Y., a Corporation of New Jersey. Filed Nov. 4, 1900. Serial No. 15,514. (No model.)

Claim.—1. The combination with a source of electric supply, of a plurality of sets of motor, the armatures of a motor of each set being connected in series, the field of each motor of one set being separately connected in series with the field of a motor of another set, and means for varying the field of one of the motors, substantially as described.

2. The combination with a source of electric supply, of a plurality of sets of motor, the armatures of each set being mechanically connected, the armatures of a motor of each set being connected in series, the field of a motor of each set being connected in series, and means for varying the field of one of the motors, substantially as described.

3. The combination with a source of electric supply, of two sets of motor, the armatures of each set being connected to a single circuit, each of the armatures of one set being connected in series with an armature of the other set, each of the fields of each set being connected in series with a field of the other set, and means for varying the field of one of the motors, substantially as described.

4. The combination with the leading conductors of a source of electric supply, of parallel circuits between said leading conductors, a plurality of sets of motor, the armatures of which sets are mechanically connected, each parallel circuit including a motor element of each set in series, and means for varying the current flowing through the motors, substantially as described.

5. The combination with a source of electric supply, of two sets of motor, the armatures of each set being mechanically connected, the armatures of a motor of each set being connected in series, the field of a motor of each set being connected in series, a circuit around the field of one of the motors, substantially as described.

6. The combination with a source of electric supply, of two sets of motor, the armatures of each set being mechanically connected, the armatures of a motor of each set being connected in series, the field of a motor of each set being connected in series, a circuit around the field of one of the motors including a variable resistance, and a permanent resistance also included in the circuit, substantially as described.

7. The combination with two sets of motor adapted to normally run at the same speed, of means for varying the field of one of the motors, and circuits and connections between the motors whereby one set of motors will speed up and the other set of motors will speed down, substantially as described.

8. The combination with two sets of motor adapted to normally run at the same speed, the armatures of each set being mechanically connected, of means for varying the field of one of the motors, and circuits and connections between the motors whereby one set of motors will speed up and the other set of armatures will speed down, substantially as described.

9. The combination with two sets of motor adapted to normally run at the same speed, the armatures of a motor of each set being connected in series, and the field of a motor of each set being connected in series, of means for varying the current of one only of the motors, and circuits and connections whereby the rate of speed between the sets of motors will be varied, substantially as described.

10. The combination with two sets of motor adapted to normally run at the same speed, the armatures of each set of motor being mechanically connected, and the fields and armatures of one set of motor being electrically connected in series, with the fields and armatures respectively of the other set of motor, of means for varying the field of one of the motors, substantially as described.

11. The combination with a source of electric supply, of a plurality of sets of motor, and circuits and connections whereby varying the ar-

rest to one motor only of one set will vary the speed of the other set of motors, substantially as described.

697,883. FURNACE. GEORGE R. GALLAGHER, New York, N. Y., assignor, by direct and mesne assignments, to the Rumney Furnace Company, New York, N. Y., a Corporation of New Jersey. Filed July 18, 1901. Serial No. 65,761. (No model.)

Claim.—1. The combination in a furnace adapted for the consumption of smoke and gases, with the side walls and the bridge-wall, of a series of ribs built into the side walls in a continuous line each the carrying in the structure a flue or opening through the back portion and parallel openings connecting the flue with the flue of the rib, said openings or flues, when the ribs are set up, forming a continuous passage-way through the side walls and the said parallel openings forming passage-ways for the delivery of the air of the flues into the combustion-chamber of the furnace, and air-flues communicating with the flues of the side walls and the flue of the bridge-wall from the rear of the furnace and exposed for the purpose of heating the air therein, substantially as set forth.

2. The combination in a furnace adapted for the consumption of smoke and gases with the side walls and the bridge-wall and flues in the side walls and delivery-openings therefrom, of a series of ribs set into the flue of the bridge-wall toward the fire-chamber, the ribs being ribs and each having an open-ended transverse flue or opening, an intake-opening and a discharge-opening communicating with one another and the discharge-opening communicating with the flue, and the flues, when the ribs are set together, forming a complete passage-way across the bridge-wall, substantially as set forth.

3. The combination in a furnace adapted for the consumption of smoke and gases, with the side walls and the bridge-wall and flues in the side walls and delivery-openings therefrom, of a series of ribs set into the flue of the bridge-wall toward the fire-chamber, the ribs being ribs and each having an open-ended transverse flue or opening, an intake-opening and a discharge-opening communicating with one another and the flues, when the ribs are set together, forming a complete passage-way across the bridge-wall, and a bridge-wall extension of tapering form and hollow, rising from the top of the bridge-wall slightly toward the rear surface of the boiler, and a flue extending forward from the back of the furnace and communicating with the flue in the ribs of the ribs, in the bridge-wall and with the flue in the bridge-wall extension, substantially as set forth.

4. The combination in a furnace adapted for the consumption of smoke and gases, with the side walls, of series of ribs set into the side walls and forming thereby continuous rows along the combustion-chamber, each rib having an open-ended flue and parallel rows of circular openings at right angles to the said flue and forming said passage-ways for the air from said flue into the combustion-chamber, the said ribs, when the ribs are set up, forming a continuous passage-way through the side walls, inclined crossing flues in the bridge-wall communicating at the ends with the flues in the ribs of the side walls, and air-flues communicating therewith from the rear of the furnace and exposed for the purpose of heating the air therein, substantially as set forth.

5. The combination in a furnace adapted for the consumption of smoke and gases with the side and front walls and the bridge-wall, of a series of ribs set into the side wall each having openings through the ribs and said openings collectively forming a continuous passage through the side wall and each rib having parallel rows of openings through the ribs communicating with the said ribs and opening into the combustion-chamber, a flue in the side wall beneath and parallel with the said ribs of ribs, a flue at the forward end of the furnace connecting the flue of the ribs of ribs and the parallel flue beneath the ribs, a flue through the bridge-wall communicating with the latter flue in the side wall and a flue extending rearward therefrom, substantially as set forth.

697,884. CIRCUIT-CONTROLLER. JOHN J. GUNN, Newark, N. J. Filed Aug. 20, 1891. Serial No. 73,002. (No model.)

Claim.—1. A compound circuit-controller comprising an electromagnet and its armature, with a second armature actuated by the magnetism induced in the regular armature, and a plurality of "make-and-break" points controlled by said armature.

2. A compound circuit-controller comprising an electromagnet and its armature, with a second armature actuated by the magnetism induced in the regular armature, the said armature being provided with contact-points.

3. In a compound circuit-controller, the combination of a plurality of circuit-controlling contacts, with a series of three or more parts of magnetic material adapted to contact said contacts, and a source of electric current adapted to induce magnetism in one of said parts, the said series being so arranged that magnetism induced in one of said parts will, in turn, induce magnetism in the second, and so on throughout the series.

4. A compound circuit-controller comprising an electromagnet and its armature, a second armature actuated by the magnetism induced in the regular armature, and a plurality of "make-and-break" points controlled by the said armature at different times for each make or break in the circuit of the electromagnet.

5. The combination of two compound circuit-controllers each comprising an electromagnet provided with two armatures actuated thereby, with two circuits each including the coils of one of said magnets, and a short-circuit for each of said magnets, the short-circuit of one magnet being controlled by one of the armatures of the other magnet.

6. The combination of two compound circuit-controllers each comprising an electromagnet provided with two armatures actuated thereby, with two circuits each including the coils of one of said magnets, two relays, each controlling one of said circuits, and a short-circuit for each of said magnets, the short-circuit of one magnet being controlled by one of the armatures of the other magnet.

7. The combination of two compound circuit-controllers each comprising an electromagnet provided with two armatures actuated thereby, with two circuits each including the coils of one of said magnets, two relays, each controlling one of said circuits, a short-circuit for each of said magnets, the short-circuit of one magnet being controlled by one of the armatures of the other magnet, and two more circuits each including one of the said relays and controlled by the other armature of one of the magnets.

8. The combination of two circuit-controllers each comprising an electromagnet provided with two armatures actuated thereby, with two circuits each including the coils of one of the said magnets, two relays each controlling one of said circuits, a short-circuit for each of said magnets, the short-circuit of one magnet being controlled by the second armature of the other magnet, two more circuits each including one of said relays and controlled by the first armature of the magnet whose circuit is controlled by the other relay, and means for adjusting the said armatures of each controller to first close the short-circuit of the other controller and then open the circuit of the relay controlling the first-named circuit of said other controller at one station of the controller-magnet, and at the other station thereof to first close the last-named relay-circuit and then open said short-circuit of the other controller.

697,885. SPRING-PUMP. GIOVANNI GONZALE, Boston, U.S.A.; J. F. LEE, Boston, and DAN FROST, Boston, Mass. Filed Nov. 12, 1891. Serial No. 82,811. (No model.)

Claim.—1. A spring-pump comprising a suitable hollow plug, a fluid-tight pipe passing through said plug, said pipe being of smaller diameter than the lower diameter of the plug, which forms a passage, a handpiece of spherical formation above the plug, said handpiece being formed in sections, a flexible valve in the handpiece, a perforated plug projecting through the spherical handpiece and connected to the valve, and a spring under the valve, substantially as described.

2. A spring-pump comprising a suitable hollow plug, a pipe passing through the plug, a handpiece or sphere extending from the plug and made in two sections, a flexible valve interposed between the meeting ends of the sections and clamped thereby, a spring to normally open the

valve, and a hollow piston fitting the valve and guided through the hand-piece, substantially as described.

3. A spring-pump comprising a plug, an exit-tube, a hollow hand-piece extending from the plug, said handpiece being formed in sections, each section having a flange, a flexible valve in the handpiece which is fastened between the flanges of the sections, a perforated projection secured to the valve and extending from the handpiece, and a spring to normally force the projection outwardly, substantially as described.

697,886. SCREW-DRIVER. JOHN A. GUNN, Hartford, Conn. Filed July 20, 1891. Serial No. 73,122. (No model.)

Claim.—1. As an article of manufacture, a screw-driver provided with a tapering blade, strengthening-rib extending longitudinally along the edge of the blade, the blade being of greater thickness at its edges than intermediate thereof on account of the presence of the rib.

2. As an article of manufacture, a screw-driver provided with a tapering blade, strengthening-rib extending longitudinally along the edge of the blade, the ribs diverging from one another as they approach the point of the blade of the screw-driver, the blade being of greater thickness at its edges than intermediate thereof on account of the presence of the rib.

3. A screw-driver consisting of a shaft, the lower portion of the shaft formed into a blade, strengthening-rib extending longitudinally along the edge of the blade, the ends of the rib extending below the point of the screw-driver, the point of the screw-driver being narrower than the breadth of the rib.

4. A screw-driver consisting of a blade, longitudinal strengthening-rib formed on the edge of the blade, the ribs diverging from each other as they approach the point of the screw-driver, the ends of the ribs extending below the point of the screw-driver and being oppositely beveled at their extreme ends.

5. A screw-driver consisting of a blade, the diameter of which gradually increases as it approaches the point, ribs formed on the gradually-diverging edges of the blade, the ribs provided with ends projecting beyond the point of the blade, the ends of the ribs adapted to enhance the sides of the screw-head and prevent the point of the screw-driver from slipping outwards in the slot in the screw-head.

697,887. RASH-LOCK. HENRIETTA E. GUNN, Boston, U.S.A. Filed Nov. 25, 1891. Serial No. 82,825. (No model.)

Claim.—1. A rash-lock comprising a ratchet secured to one end, a dog pivotedly mounted upon a parallel end, a handle for normally holding said dog by gravity in engagement with said ratchet, and a check pivoted to said handle to limit the upward movement thereof, substantially as specified.

2. A rash-lock comprising a ratchet secured to one end, a dog pivotedly mounted upon a parallel end, a handle for normally holding said dog by gravity in engagement with said ratchet, and a tapering lip adapted to engage said dog at one side of said ratchet for drawing the ratchet together.

3. A rash-lock comprising a ratchet secured to one end, a dog carried by a calibrating end and provided with a pivoting-shaft and a weighted handle extending laterally therefrom beyond the end to which

it is secured, a bearing for said shaft, rollers on said shaft at opposite ends of said bearing, and means for holding said dog in or out of engagement with said ratchet, substantially as specified.

4. A rash-lock comprising a ratchet secured to one end, a dog provided with pivoting-shaft and a handle extending laterally therefrom, a bearing for said shaft carried by a calibrating end, rollers on said shaft at opposite ends of said bearing, means for normally holding said dog in engagement with said ratchet, a check pivoted at its upper end to said handle and provided with a slotted lower end, and a securing device passing through said slot into said end, substantially as specified.

5. A rash-lock comprising a dog provided with a pivoting-shaft and a handle extending laterally therefrom beyond the end to which it is secured, a bearing for said shaft, rollers on said shaft at opposite ends of said bearing, a check pivoted at its upper end to said handle and provided with a slotted lower end, and a securing device passing through said slot into said end, and a series of notches carried by a calibrating end and decreasing in length from the upper end downwardly, substantially as specified.

6. A rash-lock comprising a ratchet secured to one end and having a series of teeth decreasing in length from the upper end downwardly, a dog provided with a pivoting-shaft and a handle extending laterally therefrom, a bearing for said shaft carried by a calibrating end, rollers on said shaft at opposite ends of said bearing, means for normally holding said dog in engagement with said ratchet, a check pivoted at its upper end to said handle and provided with a slotted lower end, and a securing device passing through said slot into said end, and a tapering lip at one side of said dog and ratchet increasing in width from the upper end downwardly, substantially as specified.

7. A rash-lock comprising a body having a series of teeth decreasing in length from the upper end downwardly, means for carrying said ratchet to a end and a tapering lip at one side of said teeth increasing in width from the upper end downwardly, substantially as specified.

8. A rash-lock for a rash-lock having a series of teeth decreasing in length from the upper end downwardly, a lip at one side of said teeth having parallel vertical walls and increasing in width from the upper end downwardly, substantially as specified.

9. In a rash-lock, the combination with an upper end, of a ratchet secured to the face of a side thereof, a lip at one side of said ratchet having a straight outer wall and an inclined inner wall, a lower end provided with a lip having a notch in which said ratchet-lip fits, and a locking-dog carried by the lower end and having a handle extended beyond the end, substantially as specified.

10. In a rash-lock, the combination with an upper end, of a ratchet having teeth decreasing in length downwardly from the top thereof secured to the face of a side thereof, a lip or flange at one side of said ratchet, a locking-dog carried by the lower end and having a handle extended beyond the end, and a bearing-plate for said locking-dog having projecting legs on opposite sides of said ratchet-lip, substantially as specified.

11. In a rash-lock, the combination with an upper end, of a ratchet secured to the face of a side thereof, a lower end provided with a lip having a notch in which said ratchet-lip fits, a locking-dog carried by the

lower end, and a bearing-plate for said locking-dog having projecting legs on opposite sides of the notch in said lip; a handle for said dog, a check secured to said handle and means for clamping said check to the end for retaining the dog in or out of engagement with said ratchet, substantially as specified.

697,888. APPARATUS FOR PURIFYING WATER FOR STEAM GENERATORS. ALEXANDER GRAY, Newcastle-upon-Tyne, England, assignor of one-half to THOMAS THOMPSON, Blackheath, England. Filed Sept. 12, 1891. Serial No. 73,145. (No model.)

Claim.—1. In a feed-water purifier, the combination of a vessel, a feed-water inlet at the bottom thereof, a blow-off pipe opening into the upper portion of said vessel, said vessel having an opening at the top communicating with the steam-space of the boiler, and a water-outlet at said vessel for delivering the feed-water to the boiler.

2. In a feed-water purifier, the combination of a vessel, a feed-water inlet at the bottom thereof, said vessel being adapted to be partially submerged in the boiler, an opening in said vessel communicating with the steam-space of the boiler, a feed-water outlet, and a blow-off outlet depending into said vessel below the water-line thereof.

3. In a feed-water purifier, the combination of a vessel, a feed-water inlet, a feed-water outlet entering the bottom of said vessel, a passage adapted to form communication between said vessel and the steam-space of a boiler, radially-disposed needles connected to said feed-water inlet, and a blow-off pipe depending into said vessel.

4. In a feed-water purifier, the combination of a vessel, a casing upon the outside of said vessel, a feed-water inlet passing through said casing and entering the bottom of said vessel, radially-disposed needles connected to said feed-water inlet, a passage adapted to form communication between said vessel and the steam-space of a boiler, and a blow-off pipe having its opening in the upper part of said vessel adapted to carry off the steam and other impurities.

5. In a feed-water purifier, the combination with a boiler, of a casing in communication with the water-space within the boiler, a vessel connected to said casing, in communication with the steam-chamber of the boiler, a feed-water pipe entering the bottom of said vessel, and a blow-off pipe having its opening in the upper part of said vessel adapted to carry off the steam from the feed-water, substantially as described.

6. An apparatus for purifying feed-water and flowing the air therefrom in steam-generators in which the feed-water of condensed steam entering the boiler passes into the apparatus comprising in combination a vessel partly submerged below the water-level and partly rising into the steam-space, with an open top and a closed bottom, through which is inserted an internal pipe connected with the feed-pipe fitted with a needle by which the impure water has a whirling agitation imparted to it, causing the oil, grease or other impurities, to be deposited upon the surface of the water in the purifier and prevented from rising with the rest of

the boiler-water, and a connecting-pipe for blowing off said deposit; substantially as described.

697,889. CUT-OFF VALVE MECHANISM. JOHN HARR, Philadelphia, Pa. Filed Jan. 20, 1899. Serial No. 99,961. (No model.)

Claim.—1. The combination of the tubular main valve, the duplex internal cut-off valve and the screw for adjusting the same, with the cut-off valve stem located on the inside of the main valve, substantially as specified.

2. The combination of the tubular main valve, the duplex internal cut-off valve and the adjusting-screw, with the cut-off valve stem located on the inside of the main valve and having connection with the adjusting-screw of the cut-off valve at a point between the two members of said valve, substantially as specified.

3. The combination of the tubular main valve, the duplex cut-off valve contained therein and the adjusting-screw for said valve having collar thereon at a point between the two members of the valve, the cut-off valve stem located on the inside of the main valve, and a two-part clamp engaging said stem and embracing the adjusting-screw between the collars of the same, substantially as specified.

697,840. CONSTRUCTION AND APPLICATION OF PISTON-VALVE. JAMES H. R. HARR, South Shields, England. Filed Apr. 20, 1899. Serial No. 97,998. (No model.)

Claim.—1. In a valve mechanism, the combination with a perforated cylinder provided with an inlet and outlet for fluid under pressure, of a piston provided with a cupped packing-ring, a perforated cupped washer fitting in said packing-ring for admitting pressure behind said packing-ring, the said packing-ring having its free edge level with the top edge of the perforated washer to prevent backing of the packing-

ring when passing the perforations in said cylinder, and means for operating said piston for controlling the delivery of fluid under pressure through the perforations in said cylinder.

2. In a quick-closing valve mechanism, the combination with a supply-pipe, and a check-valve opening from said supply-pipe; of a perforated cylinder arranged in line with said check-valve, a piston in said cylinder adapted to pass over said perforations, a piston-rod extending both ways from said piston, a second cylinder in line with the first cylinder, and a second piston in said second cylinder, connected with the first piston, a spring pressing at one end upon the first piston and at the other end upon said check-valve, and means for admitting fluid under pressure from said supply-pipe to the second cylinder and piston to operate the first piston, substantially as described.

3. In a quick-closing valve mechanism, the combination with a supply-pipe, and a check-valve opening from said supply-pipe; of a perforated cylinder arranged in line with said check-valve, a piston in said cylinder adapted to pass over said perforations, a packing-ring on said piston and means for admitting pressure behind said packing-ring, a piston-rod extending both ways from said piston, a second cylinder in line with the first cylinder, and a second piston in said second cylinder, connected with the first piston, a spring pressing at one end upon the first piston and at the other end upon said check-valve, and means for admitting fluid under pressure from said supply-pipe to the second cylinder and piston to operate the first piston, substantially as described.

697,841. DRAFT-EXHAUSTER. EMERY J. HARRIS, Tompkins, Iowa. Filed Dec. 20, 1899. Serial No. 97,732. (No model.)

Claim.—1. In a draft-exhausing apparatus, the combination with a support, of an over-bar having its inner end pivoted thereto, a draft connection carried by the free end of the over-bar, a swinging member pivoted to an intermediate portion of the over-bar, a brace having to opposite ends secured respectively to the support and the swinging member, and a draw-bar connected intermediate to the free end of the swinging member and projected at opposite sides of the support.

2. In a draft-exhausing apparatus, the combination with a relatively fixed support, of an over-bar having its inner end pivoted to the support and its outer end provided with a draft connection, a horizontally-swinging member having its outer end pivotally connected to the over-bar at a point between the middle and the inner end thereof, a draw-bar connected to the free end of the swinging member and provided with terminal draft connections, and a flexible hose having one end pivotally connected to an intermediate portion of the swinging member and its opposite end connected to the fixed support.

3. The combination with a vehicle having a pole, and a brace extending between one side of the pole and the vehicle, of an over-bar having its inner end pivoted to the pole and having its outer end pivotally connected thereto, a draft connection carried by the free end of the over-bar, a horizontal swinging member having its outer end pivotally connected to the over-bar, a draw-bar connected to the free end of the swinging member and provided with terminal draft connections, and a flexible hose having its forward end pivotally connected to an intermediate portion of the swinging member and its rear end pivotally connected to the brace.

4. A draft-exhausing device, comprising an over-bar having its inner end provided with a pivotal or telescopic connection for application to a support, a draft connection carried by the opposite free end of the bar, a horizontally-swinging member having its outer end pivotally connected to the over-bar at a point between the middle and the inner end thereof, a draft connection carried by the free end of the swinging member, a pivotal hook carried by and projected rearwardly from the swinging member, a flexible-brace connection having one end provided with a detachable connection with the swinging hook, and an attaching bracket

or clamp having a pivotal detachable connection with the other end of the flexible brace.

5. The combination with a vehicle-frame, and the draft-pole thereof, of an over-bar pivotally connected to the pole, a draft connection carried by the outer end of the over-bar, a swinging member pivotally carried by an intermediate portion of the over-bar, a flexible hose having one end connected to the swinging member and its opposite rear end connected to the frame at the opposite side of the pole, whereby the hose inclines transversely across the latter, and a draft connection applied to the free end of the swinging member.

6. In a draft-exhausing apparatus, the combination with a pole, of an over-bar having its inner end pivoted thereto, a draft connection carried by the free end of the over-bar, a swinging member pivoted to an intermediate portion of the over-bar and terminated short of the pole, a brace extending rearwardly from the swinging member and secured to the pole, and a draw-bar pivoted to the free end of the swinging member and projected at opposite sides of the pole.

7. In a draft-exhausing apparatus, the combination with a relatively fixed support, of an over-bar having its inner end pivoted thereto, a draft connection carried by the free end of the over-bar, a swinging member pivoted to an intermediate portion of the over-bar, means fixed to and carried by the support to limit the forward movement of the swinging member, and a draw-bar pivoted to the free end of the swinging member.

697,842. DYNAMITE DETONATING-CAP. ARTHUR R. HOOVER, Philadelphia, Pa. Filed Sept. 10, 1899. Renewed Sept. 7, 1901. Serial No. 74,795. (No model.)

Claim.—1. A cap for cartridges having a plurality of tangs formed about the edge of its open end, some of said tangs being bent to extend inwardly upon the interior of the cap and others bent to extend upon the exterior of the cap, substantially as described.

2. A cap for cartridges having a plurality of tangs formed about its upper edge, some of said tangs being bent and others pointed, the pointed and the bent tangs alternating each other, said bent tangs being bent outwardly to extend at right angles to the cap, and the pointed tangs bent downwardly on the inside of the cap, substantially as set forth.

697,848. MAIN GUN-TURRET. CHARLES E. HOWLAND-SUMNER, Washington, D. C., assignor of one-fourth to George H. Howard, Washington, D. C., and Samuel G. R. Cook, London, England. Filed Dec. 15, 1899. Serial No. 98,571. (No model.)

Claim.—1. Combined in a main turret structure, means for supporting the turret-pit framing and a tubular turret-pit ring superposed upon the tops of said columns, substantially as described.

2. Combined in a main turret structure, columns for supporting the turret-pit framing, a tubular turret-pit ring superposed upon the tops of said columns, and means for securing said ring to said columns, substantially as described.

3. Combined in a main turret structure, columns for supporting the turret-pit framing, concentrically disposed with reference to the axis of revolution of the turret, a tubular turret-pit ring superposed upon the tops of said columns, and means for securing said ring to said columns, substantially as described.

4. Combined in a main turret structure, columns for supporting the turret-pit framing, concentrically disposed with reference to the axis of revolution of the turret, means for securing the bases of said columns to the hull structure, a tubular turret-pit ring superposed upon the tops of said columns, and means for securing said ring to said columns, substantially as described.

5. Combined in a main turret structure, columns for supporting the turret-pit framing, concentrically disposed with reference to the axis of revolution of the turret, means for securing the bases of said columns to the hull structure, a tubular turret-pit ring concentric with the axis of revolution of the turret superposed upon the tops of said columns, and means for securing said ring to said columns, substantially as described.

6. Combined in a main turret structure, a turret-pit ring, and struts rising therefrom for supporting the turret-base, and means for connecting said struts to said ring, substantially as described.

7. Combined in a main turret structure, a turret-pit ring, struts ris-

ing therefrom for supporting the turret-base, and means for connecting said struts to said ring, substantially as described.

8. Combined in a main turret structure, a turret-pit ring, struts rising therefrom for supporting the turret-base, means for connecting said struts to said ring, and means for securing said struts to said base, substantially as described.

9. Combined in a main turret structure, a turret-pit ring concentric with the axis of revolution of the turret, struts radially disposed about the periphery of said ring and rising at an outward point to support the turret-base, means for connecting said struts to said ring, and means for securing said struts to said base, substantially as described.

10. Combined in a main turret structure, a tubular turret-pit ring concentric with the axis of revolution of the turret and having integral radial flanges extending therefrom, columns secured to and supporting said ring at the plan location of said radial flanges, gun-mounts secured to said columns beneath said radial flanges, struts extending outwardly stepped upon said flanges, means for integrating said struts, flanges and gun-mounts, and means for securing said struts to the turret-base, substantially as described.

11. Combined in a main turret structure, a tubular turret-pit ring adapted to serve the double purpose of a gun-bed and a base for the turret-pit framing, tracks superiorly attached to said ring, rolls traveling upon said tracks, and a mount traveling rotarily upon said rolls, substantially as described.

12. Combined in a main turret structure, a turret-pit ring, struts connected to and rising from said ring, and a reaction-ring attached to and integrating said struts, substantially as described.

13. Combined in a main turret structure, a turret-pit ring, struts connected to and rising from said ring, columns secured to and supporting said turret-pit ring and struts, and a reaction-ring attached to and integrating said struts, substantially as described.

14. Combined in a main turret structure, a turret-pit ring, struts connected to and rising from said ring, columns secured to and supporting said turret-pit ring and struts, a reaction-ring attached to and integrating said struts, means for attaching said reaction-ring to the deck-beams of the hull, and means for attaching said struts to the turret-base, substantially as described.

15. Combined in a main turret structure, a turret-pit ring, outwardly-extending struts connected to and rising from the periphery of said ring, a reaction-ring formed as the inverted frustum of a conical shell having an axis coincident with the axis of revolution of the turret, means for integrating said reaction-ring with said struts, and means for securing said reaction-ring to the deck-beams of the hull, substantially as described.

16. Combined in a main turret structure, a turret-pit ring, concentric with the axis of revolution of the turret, outwardly-extending struts connected to and rising from the periphery of said ring, a reaction-ring formed as the inverted frustum of a conical shell having an axis coincident with the axis of revolution of the turret, means for integrating said reaction-ring with said struts, means for securing said reaction-ring to the deck-beams of the hull, and means for securing the tops of said struts to the inwardly-inclining, conical turret-base, substantially as described.

17. In a main turret structure, a united three-part or trisectional turret proper, consisting of two end, erect conical casements, and a central erect pyramidal frustum, combined with a subjacent mount secured thereto, substantially as described.

18. In a main turret structure, a united three-part or trisectional turret proper, the same consisting of two end, erect conical casements, and an intermediate erect pyramidal frustum, combined with an attached inverted conical frustum composing the subjacent mount, substantially as described.

19. Combined in a main turret structure, an erect superior conical casement composing the front of the turret proper; an erect pyramidal frustum tangentially secured to said front conical casement; an erect superior conical casement composing the rear of the turret proper, and tangentially attached to the rear of said pyramidal frustum; and an attached inverted inferior conical frustum composing the subjacent mount, substantially as described.

20. A main turret structure comprising the following elements in combination, to wit: an erect conical casement composing the rear of the turret proper; an intermediate pyramidal frustum composing the central part of the turret proper, and secured to the two part of the said frustum element; an erect conical casement composing the front of the turret proper and secured to the two part of said second-named element; and an inverted conical frustum composing the subjacent mount, and secured to an element of the turret proper, substantially as described.

21. Combined in a main turret structure, two end, erect superior conical casements; a pyramidal frustum secured between said two end conical casements; said three united parts forming the turret proper; an attached subjacent mount consisting of an inverted inferior conical frustum; and a floor secured to the mount on the bottom plane of the apex end of said inverted frustum, substantially as described.

22. Combined in a main turret structure, two end, erect superior conical casements; an erect pyramidal frustum secured between the said two end conical casements, the three united parts forming the turret proper; a roof fitting flush within the top of the turret so peripherally defined; and an inverted inferior conical frustum secured to the forward end of the said two erect superior conical casements, substantially as described.

23. Combined in a main turret structure, two end, erect superior conical casements; a pyramidal frustum secured between said two end conical casements the three united parts forming the turret proper; a roof fitting within the top of the turret so peripherally defined; a mount consisting of an inverted inferior conical frustum secured to the forward end of the said erect superior conical casements; a mount-floor secured to the lower part of said inverted inferior conical frustum; and a gun-room floor interposed and secured between said mount-floor and the turret-roof, substantially as described.

24. In a main turret structure, a pyramidal-conical turret proper consisting of two end erect superior conical casements, and an intermediate erect pyramidal frustum secured between said two end parts; combined with a conical turret-base adapted to angularly register with the said forward erect conical casement universally at all positions of lateral train, substantially as described.

25. In a main turret structure, a pyramidal-conical turret proper consisting of two end erect superior conical casements and an intermediate erect pyramidal frustum secured between said two end parts; combined with a conical turret-base adapted to radially register at a common exterior focal angularity with the forward of the said two conical casements universally at all positions of lateral train, substantially as described.

26. In a main turret structure, a united three-part or trisectional turret proper, the same consisting of two end erect conical casements and an intermediate erect pyramidal frustum, the said parts being secured together; combined with an attached inverted conical frustum composing the subjacent mount; and a conical turret-base adapted to radially register flush at the same focal angularity with the forward end of the said two conical casements universally at all points of lateral train, substantially as described.

27. Combined in a main turret structure, a revolvable pyramidal-conical turret proper comprising two end superior conical casements with an intermediately-secured pyramidal frustum and a subjacent-secured mount; a conical turret-base; turret-pit struts; a turret-pit ring; supporting columns; and means for securing said struts to said columns and to each other, substantially as described.

28. Combined in a main turret structure, a revolvable pyramidal-conical turret proper comprising two end superior conical casements with an intermediately-secured pyramidal frustum and a subjacent-secured mount; an inwardly-inclined conical turret-base adapted to radially and finally register with the forward of said superior conical casements at all positions of lateral train; means for securing said subjacent mount to the forward end of said superior conical casements, respectively; outwardly-inclined turret-pit struts adapted to support the said inwardly-inclined conical turret-base; a reaction-ring adapted to unite said struts in

plan position; a turret-pit ring; supporting-columns; girders adapted to unite said outwardly-inclined turret-pit struts to said supporting-columns; and means for uniting said supporting-columns to said turret-pit ring, substantially as described.

697,844. MEASURING AND REGISTERING COCK FOR LIGHTS.
BENJAMIN W. HOBBS and LESTER L. CAMPBELL, Kensington, England.
Filed Jan. 27, 1902. Serial No. 91,693. (No model.)

Claim.—1. In a registering-cock, the combination with a cylinder closed at one end, a second longer cylinder closed at its rear end, surrounding and forming a projecting chamber opposite the closed end of said first cylinder, and mechanism contained in and located by said chamber for operating said inner cylinder and registering each rotation of the same.

2. In a registering-cock the combination with a cylinder closed at one end, a second longer cylinder closed at its rear end, surrounding and forming a projecting chamber opposite the closed end of said first cylinder, a bevel gear-wheel mounted on said inner cylinder, a shaft journaled transversely of said chamber, a bevel gear-wheel mounted on said shaft in engagement with said first bevel gear-wheel, a registering-wheel rotatably mounted in said chamber, means carried by said shaft for operating said wheel, means for rotating said shaft, and means for preventing the backward rotation of same.

3. In a registering-cock, the combination with a cylinder closed at one end, a second longer cylinder closed at its rear end, surrounding and forming a projecting chamber opposite the closed end of said first cylinder, a bevel gear-wheel mounted on said inner cylinder, a shaft journaled transversely of said chamber, a bevel gear-wheel mounted on said shaft in engagement with said first bevel gear-wheel, a registering-wheel rotatably mounted in said chamber provided with a plurality of laterally-projecting lugs, a key carried by said shaft for successively engaging said plurality of lugs, means for rotating said shaft, and means for preventing the backward rotation of said shaft.

697,845. CONDUIT FOR ELECTRIC OR LIKE CABLES. CARL A. W. REICHMAN, Stockholm, Sweden.
Filed Jan. 9, 1902. Serial No. 90,061.
(No model.)

Claim.—1. A conduit for electric cables comprising a plurality of tubes, transversely-arranged bars interposed between said tubes, longitudinally-arranged rods connecting the free ends of said bars and a protecting means including the tubes, substantially as and for the purpose specified.

2. A conduit for electric cables comprising a plurality of tubes formed with an inner lining of cement, a reticulated body embedded therein, an asphalt coating including said lining transversely-arranged bars interposed between said tubes, longitudinally-arranged rods connecting said bars at their ends, and a protecting means including said tubes and rods, substantially as and for the purpose specified.

697,846. IDENTIFICATION DEVICE. CHARLES A. HYDE, Philadelphia, Pa.
Filed Dec. 11, 1901. Serial No. 88,422. (No model.)

Claim.—1. An identification device consisting of a plate having a series of numbers on the face thereof, and a key adapted to be placed on

said plate and contained within said rim and provided with a plurality of recesses to receive a plurality of numbers of said series.

2. In an identification device, a plate having a series of numbers on the face thereof, and a key provided with a plurality of recesses adapted to receive a plurality of numbers of said series and having a carrying-eye.

3. An identification device, consisting of a plate having a raised rim or the margin thereof, and a series of numbers on the face of said plate, and a key adapted to be placed on said plate and contained within said rim and to receive one or more numbers of said series.

4. An identification device consisting of a plate having a raised rim and a series of numbers on the face, and a key adapted to be placed on said plate within said rim, having a plurality of recesses adapted to receive a plurality of numbers of said series, and provided with a carrying-eye.

697,847. ELECTRIC ELEVATOR SYSTEM. JOHN B. HILLMAN, Yonkers, N. Y., assignor to Otto Elevator Company, East Orange, N. J., a Corporation of New Jersey.
Filed Aug. 21, 1901. Serial No. 73,798.
(No model.)

Claim.—1. The combination with an electric motor, of controlling means therefor operated by rectified current, an alternating-current circuit, and means for supplying rectified current from said circuit to said controlling means, substantially as described.

2. The combination with an alternating-current motor, of mechanical controlling means therefor electrically operated by rectified current, and means for supplying rectified current to said controlling means, substantially as described.

3. The combination with an asynchronous motor, of controlling means therefor energized by rectified current, substantially as described.

4. The combination with a polyphase asynchronous motor, of controlling means therefor energized by rectified current, substantially as described.

5. The combination with an alternating-current supply-circuit, of a motor, mechanical controlling means therefor electrically operated by rectified current from said circuit, and means for supplying rectified current to said controlling means, substantially as described.

6. The combination with an alternating-current motor, of mechanical controlling means therefor and means for supplying rectified current to operate said controlling means, substantially as described.

7. The combination with an alternating-current supply-circuit, of a motor, controlling means therefor, and means for rectifying a portion of the current from said supply-circuit, for operating the controlling means, substantially as described.

8. The combination with an alternating-current supply-circuit, of a motor, controlling means therefor, and means for rectifying a portion of the current from said supply-circuit for energizing the controlling means, substantially as described.

9. The combination with an electric motor, of mechanical controlling means therefor, and electrolytic means for supplying rectified current to operate said controlling means, substantially as described.

10. The combination with an electric supply-circuit, of a motor, controlling means therefor, and electrolytic means for rectifying a portion of the current from said supply-circuit for operating the controlling means, substantially as described.

11. The combination with a polyphase supply-circuit, of a motor, controlling means therefor, and electrolytic means for rectifying a portion of the current from said supply-circuit, for operating the controlling means, substantially as set forth.

12. The combination with a polyphase supply-circuit, of a motor, controlling means therefor, and electrolytic cells for rectifying a portion of the current from said supply-circuit for operating the controlling means, substantially as described.

13. The combination with an alternating supply-circuit, of a motor, controlling means therefor, and electrolytic current-rectifying cells for rectifying a portion of the current from the said supply-circuit for operating the controlling means, substantially as described.

14. The combination with an alternating-current supply-circuit, of a motor, controlling means therefor, and electrolytic cells having an electrolyte of ammonium carbonate with lead and aluminum electrodes, for rectifying a portion of the current from said supply-circuit to energize the controlling means, substantially as described.

15. The combination with an alternating-current motor and its supply-circuit, of an alternating-current branch circuit containing control devices, and controlling means for the motor operated by rectified current from the supply-circuit, substantially as described.

16. The combination with an alternating-current motor and its supply-circuit, of controlling means therefor operated by rectified current, and an auxiliary alternating-current circuit, containing devices for controlling the operation of the said controlling means, substantially as described.

17. The combination of an electric motor, controlling means therefor operated by rectified current, and an auxiliary alternating-current circuit controlling said controlling means, substantially as described.

18. The combination with an alternating-current supply-circuit, of a motor, controlling means therefor, means for supplying rectified current to said controlling means, and an auxiliary alternating-current circuit for controlling the supply of said rectified current, substantially as described.

19. The combination with an alternating-current supply-circuit, of a motor, mechanical controlling means therefor, means for operating said controlling means by rectified current, means for supplying rectified current to said controlling means, and means for controlling the operation of the controlling means, substantially as described.

20. The combination with a polyphase supply-circuit, of a polyphase motor, controlling means therefor, means for rectifying a portion of the current from the supply-circuit for operating said controlling means, and an auxiliary alternating circuit connected to the supply-circuit, for controlling the operation of the controlling means, substantially as described.

21. The combination of an electric motor, controlling means therefor, electrolytic means for supplying rectified current to operate the controlling means, and an auxiliary alternating-current circuit for controlling said controlling means, substantially as described.

22. The combination with an electric supply-circuit, of a motor, controlling means therefor, electrolytic means for rectifying a portion of the current from said supply-circuit, for operating the controlling means, and means for controlling the operation of the controlling means, substantially as described.

23. The combination with a two-phase three-wire circuit, of sets of electrolytic cells for rectifying one phase of the current, sets of cells for rectifying the other phase of the current, and connections whereby a rectified current is obtained, substantially as described.

24. The combination with a two-phase three-wire circuit, of sets of electrolytic cells connected in parallel to rectify both impulses of each phase of the current, connections between the parallel sides of each set of cells and connections between said connections, substantially as described.

25. The combination with a two-phase three-wire circuit, of sets of electrolytic cells connected in parallel to rectify both impulses of each phase of the current, connections between the parallel sides of each set of cells and connections including electrostatic devices between said connections, substantially as described.

26. The combination with a polyphase circuit, of sets of electrolytic

cells for rectifying each phase of the current, and connections whereby a rectified current is obtained, substantially as described.

27. In an elevator, the combination of the car, an electric motor for operating the same, controlling means for said motor operated by rectified current, an alternating-current circuit, and means for supplying rectified current from said circuit to said controlling means, substantially as described.

28. In an elevator, the combination with the car and an electric motor for operating the same, of reversing means for the motor and a brake controlled by rectified current, an alternating-current circuit, and means for supplying rectified current from said circuit to the reversing means for the motor and the brake, substantially as described.

29. In an elevator, the combination of the car, an electric motor for operating the same, and reversing means for the motor controlled by rectified current, substantially as described.

30. In an elevator, the combination of the car, an electric motor therefor, an alternating-current supply-circuit, mechanical motor-controlling means electrically operated by rectified current from said supply-circuit, and means for supplying rectified current to said controlling means, substantially as described.

31. In an elevator, the combination of the car, an electric motor therefor, an alternating-current supply-circuit and motor-controlling circuit, including reversing and brake magnets, energized by rectified current from said supply-circuit, substantially as described.

32. In an elevator, the combination of the car, an electric motor therefor, mechanical controlling means for the motor, and electrolytic means for supplying rectified current to operate said controlling means, substantially as described.

33. In an elevator, the combination of the car, an electric motor therefor, an alternating-current supply-circuit, controlling means for the motor, and electrolytic means for rectifying a portion of the current from said supply-circuit for operating the controlling means, substantially as described.

34. In an elevator, the combination of the car, an electric motor therefor, a polyphase supply-circuit, controlling means for the motor, and electrolytic cells for rectifying a portion of the current from said supply-circuit for operating the controlling means, substantially as described.

35. In an elevator, the combination with the car, of an electric motor therefor, an alternating-current supply-circuit, controlling means for the motor, and electrolytic cells having an electrolyte of ammonium carbonate with lead and aluminium electrodes, for rectifying a portion of the current from said supply-circuit to energize the controlling-circuits, substantially as described.

36. In an elevator, the combination of the car, an alternating-current motor for running the same, a supply-circuit for the motor, an alternating-current circuit containing push-buttons and switches, and controlling-circuits for the motor energized by rectified current from the supply-circuit, substantially as described.

37. In an elevator, the combination of the car, an electric motor therefor, a brake and reversing-switch for the motor, operated by rectified current, and an auxiliary alternating-current circuit, containing circuit-controllers, for controlling the operation of the brake and reversing-switch, substantially as described.

38. In an elevator, the combination of the car, an alternating-current motor therefor, a supply-circuit for the motor, controlling-circuits for the motor, and electrolytic means for rectifying a portion of the current from the supply-circuit to energize the controlling-circuits, substantially as described.

39. In an elevator, the combination of the car, an electric motor therefor, a brake, reversing-switch and starting resistance for the motor, operated by rectified current, and an auxiliary alternating-current circuit containing circuit-controllers for controlling the operation of the said brake, reversing-switch and starting resistance, substantially as described.

40. In an electric elevator, the combination of the car, an electric motor therefor, a brake and reversing-switch for the motor, electrolytic means for supplying rectified current for the operation of the brake and reversing-switch, and an auxiliary alternating-current circuit containing circuit-controllers for controlling the operation of the brake and reversing-switch, substantially as described.

41. In an apparatus for controlling elevators, the combination with the car and an elevator-motor, of motor-controlling means operated by rectified current, and an alternating-current circuit, including switches on the car, for controlling the operation of the motor-controlling means, substantially as described.

42. In an apparatus for controlling elevators, the combination with the car and an elevator-motor, of motor-controlling means, electrolytic means for supplying rectified current to the motor-controlling means, and an alternating-current circuit including switches on the car, for controlling the operation of the motor-controlling means, substantially as described.

43. In an apparatus for controlling elevators, the combination with

the car and an elevator-motor, of motor-controlling circuits energized by rectified current, and a push-button circuit for the car and landings energized by alternating current and controlling the motor-controlling circuits, substantially as described.

44. In an apparatus for controlling elevators, the combination with the car and an alternating-current elevator-motor, of a supply-circuit for the motor, motor-controlling circuits, electrolytic cells for rectifying current from the supply-circuit, means for energizing the motor-controlling circuits with rectified current, and an alternating push-button circuit including the car and landings and controlling the supply of rectified current, substantially as described.

45. In an elevator, the combination of the car, and an electric motor, of controlling-circuits for the motor, energized by rectified current, circuit-closures in the motor-controlling circuits, an alternating-current push-button circuit, and means jointly controlled by the motor-controlling circuits and push-button circuit for operating said circuit-closures, substantially as described.

46. In an elevator, the combination of the car, and an electric motor, controlling-circuits for the motor energized by rectified current, circuit-closures in the controlling-circuits, an alternating-current push-button circuit including a circuit-breaker, means jointly controlled by the motor-controlling circuits and push-button circuit, for operating the circuit-closures, and means controlled by the motor-controlling circuits for operating said circuit-breaker, substantially as described.

47. In an elevator, the combination of the car and an alternating-current motor, circuits including current-rectifying means, circuit-closures in said circuits, motor-controlling circuits supplied with rectified current, an alternating-current push-button circuit, and means jointly controlled by the motor-controlling circuits and push-button circuit for operating said circuit-closures, substantially as described.

48. The combination with an alternating-current circuit, of a current-rectifier, circuits therefor including circuit-closures, and means jointly controlled by alternating and rectified current for operating said circuit-closures, substantially as described.

49. In an elevator, the combination of the car and an alternating-current motor, circuits including current-rectifying means, circuit-closures in said circuits, motor-controlling circuits supplied with rectified current, an alternating-current push-button circuit, and means jointly controlled by alternating and rectified current for operating said circuit-closures, substantially as described.

50. In an elevator, the combination of the car and an electric motor, controlling-circuits for the motor, supplied with rectified current, circuit-closures in the motor-controlling circuits, an alternating-current push-button circuit, and means jointly controlled by rectified and alternating current for operating said circuit-closures, substantially as described.

51. The combination with an asynchronous motor having a short-circuited armature including starting resistance in the rotor-circuit, of means operated by rectified current for cutting out said resistance on starting, substantially as described.

52. The combination with an asynchronous motor having a short-circuited armature including a starting resistance in the rotor-circuit, of a supply-circuit, electrolytic means for rectifying a portion of the current from the supply-circuit, and means controlled by the rectified current for cutting out the said resistance on starting, substantially as described.

53. In an elevator, the combination of a car and an asynchronous elevator-motor, a supply-circuit, electrolytic means for rectifying a portion of the current from the supply-circuit, and means controlled by the rectified current for cutting out the resistance from the rotor-circuit on starting, substantially as described.

54. In an elevator, the combination of a car and an asynchronous elevator-motor, a supply-circuit, electrolytic means for rectifying a portion of the current from the supply-circuit, and means controlled by the rectified current for cutting out resistance from the rotor-circuit on starting, and means for controlling the rectified current, substantially as described.

697,848. DRAWING-BOARD. EDGAR E. JARVIS, Toronto, Canada.
Filed Nov. 2, 1901. Serial No. 81,000. (No model.)

Claim.—11. In a drawing-board, independent side bars, hinged at one end to the board and extending from underneath the board to a point outside of the board as in

to form a rest for the bars and with the pivot of the hinge on the outer lower edge, each bar being so arranged that they fold inwardly and downwardly from such pivot, so as to abut the edges of the board and draw down the paper overhanging such edges as specified.

2. In a drawing-board independent side bars, hinges extending from underneath the board to a point outside of the board, so as to form rests for the bars and with the pivot of the hinge on the outer lower edge, the said board being provided with an underlying stop or projection extending lengthwise of the lower portion of the edge of the board, and the said bars being provided with an overlying stop or projection designed to fit over the underlying stop on the board, so that the paper is gripped and securely held as specified.

3. In a drawing-board, the board, independent side bars, hinges extending from underneath the board to a point outside of the board, so as to form rests for the bars and with the pivot of the hinge on the outer lower edge, the said board being provided with an underlying stop or projection extending lengthwise of the lower portion of the edge of the board and the said bars being provided with an overlying stop or projection designed to fit over the underlying stops on the board, so that the paper is drawn and stretched and a gripping device extending along between such overlying and underlying portion as specified.

4. The combination with the central board, of the bars forming a boundary for the frame, hinges having one member secured to the board and the other member secured to the bars, so that the pivot of the hinge is outermost, the member of the hinge secured to the bar being above the surface thereof and the member of the hinge secured to the board having a band whereby the inner end is securely fastened close to the surface of the board as and for the purpose specified.

5. The combination with the board and the independent bars suitably connected thereto at the outside edges, of pressure-plates connected to two bars and extending over the end edges of the two existing bars and adjusting means for securing the aforesaid bars in position as and for the purpose specified.

697,849. INDICATING MECHANISM FOR POST-OFFICE BOXES.
THOMAS F. KELLY, Admr. Invt. Filed June 10, 1901. Serial No. 93,994.
(No model.)

Claim.—1. The combination with a plurality of post-office boxes, of an indicating device for each box, and electrical means for operating said indicating device, said means including electromagnetic devices operatively connected with the indicating device, electrical connections for connecting said electromagnetic devices with a source of electrical energy, and circuit-closing devices for controlling said electromagnetic devices whereby the indicating devices may be simultaneously operated and severally restored to initial position.

2. The combination with a plurality of post-office boxes having each a hinged door, of an indicating device carried by each door, and means for operating said indicating device, said means being operatively connected with the indicating device when the doors are open as well as when they are closed.

3. The combination with a plurality of post-office boxes, having movable doors closing the fronts thereof, of an indicating device carried by each door and means for simultaneously displaying all of said indicating devices and means for severally restoring them to initial position.

4. The combination with a plurality of post-office boxes having movable doors, of an indicating device carried by each door, electrical means for simultaneously displaying all of said indicating devices, and means whereby said devices may be severally restored to initial position.

5. The combination with a plurality of post-office boxes having movable doors, indicating devices carried by said doors, double solenoids also carried by said doors having their cores connected with the indicating devices, and electrical connections for separately energizing the members of said double solenoids whereby the cores are moved in opposite directions.

6. The combination with a plurality of post-office boxes, of indicating devices therefor, a double solenoid for each box, having its core connected

with the corresponding indicating device, electrical connections for simultaneously energizing one of the members of all the double solenoids, and electrical connections for severally energizing the other members.

697,850. LOCOMOTIVE DRIVING-WHEEL. LOWELL E. KINTON, Allegheny, Pa. Filed Feb. 4, 1902. Serial No. 92,595. (No model.)

Claim.—1. In a locomotive, a driving-wheel having two counterbalances of unequal weights, on different sides of the axle.

2. In a locomotive, a driving-wheel having two counterbalances of unequal weights, one on the crank-pin side and one opposite thereto.

3. In a locomotive, a driving-wheel having two counterbalances of unequal weights, the heavier being opposite the crank-pin.

4. In a locomotive, the combination with a main driving-wheel and one or more coupled wheels, of two counterbalances on each of said coupled wheels, the weight of one counterbalance being less than that of the other by an amount equal to the weights of the crank-rod, pin, and the proportional weight of the rod on that pin.

5. In a locomotive, the combination with a main driving-wheel and its connected parts, of one or more coupled wheels, and a counterbalance for said coupled wheel of such weight that the aggregate of its weight and those of the coupled wheel and its connected revolving parts shall be substantially equal to that of the main driving-wheel, its counterbalance and the connected revolving parts.

697,851. NON-REFILLABLE BOTTLE. FREDERICK KLEIN, New York, N. Y. Filed Dec. 27, 1901. Serial No. 87,412. (No model.)

Claim.—1. A bottle provided with a neck formed in a series of connected members at angles to each other, the mouth or outlet member extending across the face of one of the intermediate members, as specified.

2. A bottle the neck of which is formed in a series of connected members at angles to each other, the mouth or outlet member extending across the face of one of the intermediate members with an upward inclination, as and for the purpose specified.

3. A bottle provided with a neck formed by a series of connected members at angles to each other, and approximating in shape that of a figure 4, as described.

4. A bottle provided with a neck having an upwardly-projecting member, an outwardly and downwardly projecting member, and an inwardly-projecting member extending across the upwardly-projecting member, as set forth.

5. A bottle provided with a neck having an upwardly and outwardly projecting member, an outwardly and downwardly projecting member, and an inwardly and upwardly projecting member, as set forth.

6. A bottle cap or outlet section, comprising a straight member, an upwardly and outwardly inclined member, outwardly and downwardly inclined member, and an inwardly and upwardly inclined member, as set forth.

7. A bottle, comprising a body having a socket member, and a cap or outlet section, comprising a straight member secured to the socket member of the bottle, an upwardly and outwardly inclined member, an outwardly and downwardly inclined member and an inwardly and upwardly inclined member, as set forth.

8. A bottle, comprising a body having an interiorly-threaded socket member, a cap or outlet section, consisting of a straight member having an exteriorly-threaded extension screwing into the bottom section, an upwardly and outwardly inclined member, an outwardly and downwardly inclined member, and an inwardly and upwardly inclined member, and means whereby the cap or outlet section is prevented from being unscrewed from the body, as set forth.

9. A bottle, comprising a body having an interiorly-threaded socket member, a glass cap or outlet section formed of a series of connected members at angles to each other, one of the members having an exteriorly-threaded extension screwing into the socket member of the body, the cap and body at their point of juncture being provided with an annular groove, and a ring in said groove, as set forth.

687,852. WORK-REST FOR GRINDING-MACHINES. ABRAHAM S. LAUREN, Waynesboro, Pa. Filed Sept. 7, 1901. Serial No. 74,619. (No model.)

Claim.—1. In a work-rest for grinding-machines, the combination of a base or support, a bar pivoted between its ends at one side of the work provided with a work-engaging bearing on one end thereof and an adjustable weight at its other end.

2. In a work-rest for grinding-machines, the combination of a base or support, a bar pivoted between its ends at one side of the work provided with a work-engaging bearing at one end thereof, and an adjustable stop controlling the elevation of said bearing.

3. In a work-rest for grinding-machines, the combination of a base or support, a bar with a work-engaging bearing at one end thereof, said bar pivoted on said base, an adjustable stop controlling the elevation of said bearing and an adjustable weight on the opposite side of the pivot in said bar from said work-engaging bearing.

4. In a work-rest for grinding-machines, the combination of a base or support, and a pivoted bar with a work-engaging bearing at one end thereof, the pivot of said bar engaging an oblique surface.

5. In a work-rest for grinding-machines, the combination of a bar having a work-engaging bearing at one end thereof, an adjustable weight on the other end, and a central pivot engaging an adjustable oblique surface.

6. In a work-rest for grinding-machines, the combination of a bar having a work-engaging bearing, an adjustable weight, a pivot engaging an oblique surface, and an adjustable stop engaging said pivot.

7. In a work-rest for grinding-machines the combination of a bar having a work-engaging bearing, and a yieldingly-mounted clip to engage the top of the work.

8. In a work-rest for grinding-machines, the combination of a pivoted bar having a work-engaging bearing, an adjustable weight on said bar, and a clip to engage the top of the work.

9. In a work-rest for grinding-machines the combination of a bar

having a work-engaging bearing, a pivot in said bar, said pivot engaging an oblique surface, and a clip to engage the work.

10. In a work-rest for grinding-machines the combination of a pivoted bar, and a work-engaging bearing mounted on the end thereof, said bearing having a hook by which it is supported to said bar.

11. In a work-rest for grinding-machines, a bar having a work-engaging bearing at one end, a pivot approximately at its center, an adjustable weight on the other end and means for clamping said bar rigidly when required.

12. In a work-rest for grinding-machines a base or support having a bar pivoted thereto, said bar having a work-engaging bearing, said pivot engaging an oblique surface, an adjustable stop engaging said pivot, an adjustable weight on said bar and a stop to control the upward position of said work-engaging bearing.

13. In a work-rest for grinding-machines, a base or support, having a bar pivoted thereto, said bar having a work-engaging bearing, the pivot of said bar engaging an oblique surface, an adjustable stop engaging said pivot, an adjustable weight on said bar, a stop to control the upward motion of said work-engaging bearing, and a clip to engage the top of the work.

14. In a work-rest for grinding-machines, a base or support, having a bar pivoted thereto, said bar having a work-engaging bearing, said pivot engaging an oblique surface, an adjustable weight on said bar, an adjustable stop engaging said pivot, a stop to control the upward motion of said work-engaging bearing and means for locking said bar in a rigid position when required.

15. In a work-rest for grinding-machines, a base or support formed like an open box having sides to which a bar is pivoted, said bar having a work-engaging bearing on one end, a weight on the other end of said bar, said parts being contained in said box which thus forms a protection to said bar so that its free motion cannot be interfered with.

16. In a work-rest for grinding-machines, a base or support, a bar pivoted thereto, said bar having a work-engaging bearing, said pivot engaging an adjustable oblique surface, an adjustable weight on said bar, an adjustable stop engaging said pivot, an adjustable stop to control the upward motion of said work-engaging bearing, a clip to engage the top of the work and means for locking said bar in a rigid position when required.

17. In a work-rest for grinding-machines, a pivoted bar, a work-engaging bearing on one end thereof, a roller on said pivot engaging an oblique surface, and means for holding the bearing yieldingly to the work attached to the other end of said bar.

18. In a work-rest for grinding-machines, the combination of a base or support, a pivoted bar with a work-engaging bearing at one end thereof, the pivot engaging an oblique surface and an adjustable weight at the other end of said bar.

19. In a work-rest for grinding-machines the combination of a base or support, a pivoted bar with a work-engaging bearing at one end thereof, the pivot engaging an adjustable oblique surface, and means for holding said bearing yieldingly in engagement with the work.

20. In a work-rest for grinding-machines, the combination of a base or support, a bar with a work-engaging bearing, said bar pivoted on an oblique surface, a stop controlling the upward motion of said bearing, and means for holding said bar yieldingly in engagement with the work.

21. In a work-rest for grinding-machines, the combination of a base or support, a bar with a work-engaging bearing, said bar being pivoted on an adjustable oblique surface, a stop controlling the upward motion of said bearing, and means for holding said bearing yieldingly in engagement with the work.

22. In a work-rest for grinding-machines, the combination of a base or support, a bar with a work-engaging bearing, said bar pivoted on an oblique surface, an adjustable stop engaging said pivot controlling the forward position of said bearing and means for holding said bearing yieldingly in engagement with the work.

23. In a work-rest for grinding-machines, the combination of a bar with a work-engaging bearing, said bar being pivoted on an adjustable oblique surface and adjustable stops engaging said pivot controlling the forward position of said bar, a stop controlling the upward position of said bearing, means for holding said bearing yieldingly in engagement with the work and a clip to engage the top of said work.

24. In a work-rest for grinding-machines, a pivot-bar with a work-engaging bearing, a clip engaging the top of the work and a spring for holding said clip yieldingly to said work.

25. In a work-rest for grinding-machines, a work-engaging bearing, means for holding said bearing to the work, a clip engaging the top of the work, and a spring holding said clip yieldingly to said work.

26. In a work-rest for grinding-machines, a work-engaging bearing arranged with a hook as shown to attach to the end of a bar with means for holding said bearing yieldingly in contact with the work, a clip for engaging the top of the work and also the top of the bearing by which said bearing is held in position.

27. A work-rest for grinding-machines comprising a bar having a work-engaging bearing, said bar having a slotted plug, said slot forming an oblique surface which engages with the pivot in the support.

28. A work-rest for grinding-machines comprising a bar having a work-engaging bearing, said bar having a slotted plug, said slot forming an oblique surface which engages with the pivot in the support, said plug having a pin by which it is turned to adjust the obliquity as desired, a screw for locking said plug and a screw-stop engaging the pivot passing through the pin.

29. A work-rest for grinding-machines comprising a bar having a work-engaging bearing, said bar having a slotted plug, said slot forming an oblique surface which engages with a pivot formed with a roller, said roller having flanges at each end to hold the bar against side movement.

30. A work-rest for grinding-machines comprising a bar having a work-engaging bearing, said bar having a slotted plug, said slot forming an oblique surface, said surface bearing upon a pivot, said plug being adjustable in a rotary direction whereby the forward tension of the bearing against the work is adjusted, and an adjustable weight whereby the upward tension is adjusted.

31. A work-rest for grinding-machines, comprising a bar having a work-engaging bearing, said bar having a slotted plug, said slot forming an oblique surface, said surface bearing upon a pivot, said plug being adjustable in a rotary direction whereby the forward tension of the bearing against the work is adjusted, and stops for limiting the movement of said bar.

32. A work-rest for grinding-machines, comprising a bar having a work-engaging bearing, said bar having a slotted plug forming an oblique surface, said surface bearing upon a pivot, said plug being adjustable in a rotary direction, whereby the forward tension of the bearing against the work is adjusted, means by which the upward tension on the work is produced, stops for limiting the movement of said bar and a clamping-screw by which said bar is rigidly locked.

33. A work-rest for grinding-machines, comprising a bar pivoted and mounted to slide on an oblique surface which is adjustable as to pitch, substantially as set forth.

34. A work-rest for grinding-machines comprising a bar pivoted and mounted to slide on an oblique surface under an adjustable pressure, substantially as set forth.

35. A work-rest for grinding-machines comprising a support provided with the work-engaging bearing mounted to both pivot and slide toward the work under adjustable pressure, substantially as set forth.

36. In a work-rest for grinding-machines, the combination of the frame, the pivoted bar mounted therein, means for automatically adjusting said bar toward the work, the work-engaging bearing on said bar, and controlling-stops, substantially as set forth.

37. In a work-rest for grinding-machines, the combination with the work-engaging bearing, of a yieldingly-mounted clip or finger arranged to engage the upper side of the work lightly, substantially as set forth.

697,858. WORK-REST FOR GRINDING-MACHINES. ABRAHAM B. LAZER, Waynesboro, Pa. Filed Sept. 12, 1901. Serial No. 74,682. (No Model.)

Claim.—1. In a work-rest for grinding-machines, the combination, of the supporting-frame, sliding bars therein and provided with the work-engaging bearings arranged to bear against the work from different directions, and means operated by a single device for locking said bars simultaneously, substantially as set forth.

2. In a work-rest for grinding-machines, the combination of the supporting-frame mounted at one side of the work, sliding bars mounted therein to be operated and locked simultaneously by a single device, and provided with the work-engaging faces arranged to bear against the work from different directions.

3. In a work-rest for grinding-machines, the combination, of the supporting-frame, sliding bars mounted therein and provided with the work-engaging faces, means for normally forcing said bars toward the work, and clamping means operated by a single device for locking them simultaneously in desired position, substantially as set forth.

4. In a work-rest for grinding-machines, the combination, of the supporting-frame, and bars with the rest-faces mounted to slide in ways extending in radial lines from the work, and means for simultaneously clamping said bars.

5. In a work-rest for grinding-machines, the combination, of the supporting-frame, and parts provided with the rest-faces arranged in said frame to bear against the work in different directions, and means for simultaneously clamping said parts.

6. In a work-rest for grinding-machines, the combination, of the supporting-frame containing ways, bars with rest-faces mounted therein, springs for forcing said bars toward the work, a clamping-plate for simultaneously securing them, and means for operating said clamping-plate.

7. A work-rest for grinding-machines comprising a plurality of parts with rest-faces arranged to bear against the work from different directions, and means for operating and locking them simultaneously.

8. In a grinding-machine, the combination of the table carrying the grinding-wheel, and a work-rest supported thereon with the point of rest bearing against the work directly opposite the operating-face of said grinding-wheel but with its advance edge somewhat behind the advance edge of the said wheel, substantially as set forth.

9. In a grinding-machine, the combination, of the table carrying the grinding-wheel, the work-rest supported on said table, the point of rest bearing against the work being arranged directly opposite the operating-face of said wheel but with its advance edge slightly behind the advance edge of said wheel, and means for adjusting said point of rest to the work.

10. In a grinding-machine, the combination, of the table carrying the grinding-wheel, the work-rest supported on said table, the rest being arranged with its face opposite the face of the grinding-wheel but slightly behind its advance edge, means for adjusting said rest to the work, and means for clamping it rigidly in adjusted position, substantially as set forth.

11. In a work-rest for grinding-machines, the combination, of the supporting-frame, the sliding bars therein provided with the rest-faces, means for forcing said bars to the work, and a clamping-plate bearing against said bars and adjustably secured to the frame by a transverse pin having a depression with a tapered side, and a screw with a tapered point mounted in said frame with said point adapted to engage said depression and bear against the tapered side, whereby said plate may be forced in to clamp said bars against the frame, substantially as set forth.

697,864. AUTOMATIC WORK-REST FOR GRINDING-MACHINES. ABRAHAM B. LAZER, Waynesboro, Pa. Filed Sept. 11, 1901. Serial No. 73,022. (No Model.)

Claim.—1. In a work-rest, the combination of the points of rest adjustably supported, and means for automatically clamping them in position.

2. In a work-rest for grinding-machines, the combination of the points of rest adjustably supported, means for automatically adjusting them, and means for automatically locking them, substantially as set forth.

3. In a work-rest for grinding-machines, the combination, of the supporting-frame, points of rest carried on parts mounted in said frame to move on circular lines, clamping means, and means for automatically operating said locking means, substantially as set forth.

4. In a work-rest for grinding-machines, the combination, of the supporting-frame, blocks mounted on circular connections therein and carrying the points of rest, means for clamping said parts in place, and means for automatically operating said clamping mechanism.

5. In a work-rest for grinding-machines, the combination, of the supporting parts, the blocks carrying the points of rest mounted therein on circular connections, a wedge mounted between adjacent faces of portions of said blocks beyond said circular connections, means for forcing said wedge forward, means for clamping said parts against the operation of said wedge, and means for automatically operating said clamping mechanism, substantially as set forth.

6. In a work-rest for grinding-machines, the combination, of the supporting parts, the blocks carrying the points of rest mounted to be adjusted toward or away from each other at their ends, means for effecting said adjustment, means for clamping said parts in adjusted position, and means for operating said clamping mechanism automatically, substantially as set forth.

7. In a work-rest for grinding-machines, the combination, of the supporting parts, the blocks carrying the points of rest mounted therein to move on circular connections, means for adjusting said blocks, and means for securing them in adjusted position, substantially as set forth.

8. In a work-rest for grinding-machines, the combination, of the supporting parts, parts carrying the points of rest mounted therein to be adjusted on circular tracks, and means for securing them in the desired position, substantially as set forth.

9. In a work-rest for grinding-machines, the combination, of the supporting parts, the parts carrying the points of rest mounted therein to be moved on circular lines to approach or recede from each other at their ends, substantially as set forth.

10. In a work-rest for grinding-machines, the combination, of the supporting parts, the moving parts carrying the points of rest mounted therein, and a spring-wedge for forcing the said parts to the work, substantially as set forth.

11. In a work-rest for grinding-machines, the combination, of the support C, the plate C' attached thereto, the blocks 1 and 2 mounted between them by interengaging circular grooves and flanges, the rest-blocks mounted thereon, the clamping-belt, the spring-wedge, the arm 7 with nut on the clamping-belt, and the cam on the machine with which said arm engages.

12. In a work-rest, the combination of the supporting parts, the parts carrying the points of rest mounted therein to move on circular connections, and a spring-wedge for operating them provided with a handle by which it may be manipulated against the operation of the spring, substantially as set forth.

697,855. BELT-BUCKLE. ALMA E. LEE, Lynn, Mass., assignor of one-half to Jacob F. Frost, Lynn, Mass. Filed Mar. 25, 1901. Serial No. 62,714. (No model.)

Claim.—1. The combination with a belt or girdle, of a hook on the one end, and a buckle connecting the ends of the belt or girdle, said buckle being adapted to be connected with the hook on the one end; substantially as described.

2. The combination with a belt or girdle, of a buckle for connecting the ends thereof, said buckle comprising an ornamental plate or shield and an endless ring connected to the back of said shield and forming the connection between the ends of the belt or girdle, substantially as described.

3. The combination with a belt or girdle, of a buckle for connecting the ends thereof, said buckle comprising an ornamental plate or shield, and a ring having downturned lugs secured to the back of said ornamental plate or shield, substantially as described.

4. The combination with a belt or girdle, of a buckle connecting the ends thereof said buckle comprising an ornamental plate or shield, and an endless ring having downturned lugs secured to the back of the ornamental plate or shield, the ring between the lugs forming two curved hook-engaging sections for the ends of the belt, and an outwardly-bent section to engage a hook on the one end, substantially as described.

697,856. CONTACT FOR ELECTRIC GLOW-LAMPS. ARMAND LEVINE, Paris, France, assignor to Electric Lighting Board, Limited, London, England. Filed Nov. 11, 1901. Serial No. 61,914. (No model.)

Claim.—1. An electrical lamp having a sheath, insulating material inclosed by said sheath, a conducting member having a head embedded in said insulating material, and projecting from the sheath, leading-in wires connected respectively with the sheath and conducting member, in combination with a pair of separate conductors passable by said conduct-

ing member and one of them being adapted for electrical connection with the sheath.

2. The combination of a pair of separate framework conductors, and an electrical lamp, said lamp having a projecting conducting member adapted to extend through the openings in said conductors, and a sheath, the sheath and conducting member being insulated from each other, and leading-in wires connected respectively with the sheath and conducting member.

3. The combination of a pair of framework conductors, one of which is covered with insulating material, an electric lamp having a projecting conducting member, a sheath insulated from said conducting member, said conducting member being adapted to extend through openings in said conductors, and leading-in wires connected respectively with the sheath and conducting member, and a part in rotatable connection with the lamp and electrically connected with the sheath thereof and having a projection adapted to penetrate the said insulating material and the conductor to which the same is attached.

4. The combination of separate woven-wire conductors and an electrical lamp having a projecting member adapted to extend through the conductors and a sheath, the sheath and conducting member being insulated from each other.

697,857. CIRCULAR SAW. BERNARD LICHTE, Buda, Austria-Hungary. Filed Apr. 3, 1902. Serial No. 11,778. (No model.)

Claim.—1. In a machine of the class described, the combination with a suitable table, a saw and a carriage reciprocable on the table, of devices mounted independently of the carriage and operated thereby to engage and shift the work from the saw, substantially as described.

2. In a machine of the class described, the combination with a suitable table, a saw and a carriage reciprocable on the table, of devices to exert pressure on and hold the work in position to be cut by the saw, and devices independent of and operated by the carriage to engage and shift the work from the saw against the action of the holding devices, substantially as described.

3. In a machine of the class described, the combination with a suitable table and saw, of a reciprocable carriage, a guide to regulate the thickness of material to be cut, means for holding the material against said guide, a device for holding it down on the table and a stop mechanism for said carriage arranged to be operated by said means to stop the carriage, substantially as described.

4. In a machine of the class described, the combination with a suitable table and saw, of a reciprocable carriage, a guide, means for holding the material to be cut against said guide, a device for holding the material down on the table, mechanism for shifting the material from the saw at the end of each cut and operated by the carriage and a stop mechanism arranged to be operated by the means for holding the material against the guide when substantially all of the material has been cut in order to stop said carriage, substantially as described.

5. In a machine of the class described, a reciprocable carriage, a rack thereon, a gear-wheel arranged to engage the rack to drive the carriage forward, a clutch on the shaft arranged to engage said gear-wheel, a clutch-operating mechanism arranged to automatically disengage said shaft and wheel, a weight arranged to return the carriage to position to start its forward travel, a spring to hold the work, a lever to hold the clutch out of engagement and a projection 14 moved by said spring to move the lever to stop the machine, substantially as described.

6. In a machine of the class described, a reciprocable carriage, a wheel arranged to drive said carriage forward, a driving-shaft and a clutch thereon, a clutch device on the shaft arranged to engage said wheel, a clutch-operating mechanism arranged to disengage said clutch and wheel at the end of its forward travel and connect them again at the end of its rearward travel, a weight arranged to move the carriage rearward, and means operated from the carriage to hold the clutch permanently disengaged, substantially as described.

7. In a machine of the class described, a reciprocable carriage, a rack thereon, a driving-shaft, a spring-actuated clutch thereon, a gear-wheel engaging the rack and arranged to be coupled to the shaft by said clutch, a weighted ball-crank lever arranged to move the clutch against the stress of its spring, a second lever operated from the carriage arranged to disengage the ball-crank lever to allow the clutch to engage the gear-wheel and to disengage it again at the end of the forward travel of the carriage and means for causing the return travel of said table, substantially as described.

8. In a machine of the class described, a reciprocable carriage, and a rack and gear-wheel for moving it forward, a driven spring-held clutch arranged to engage said wheel, a lever acting on the clutch, a weighted ball-crank lever acting on the latter, means at one end of the carriage to engage the first-mentioned lever to allow the engagement of clutch and wheel, a latch to lock the first-mentioned one when moved, and a device on the carriage, whereby said latch is moved to allow the weighted ball-crank lever to act on the first-mentioned one to move the clutch out of engagement with the wheel and against the stress of its spring, substantially as described.

9. In a machine of the class described, the combination with a table, a reciprocable carriage thereon, a saw and mechanism to reciprocate the carriage, of cam-fingers connected together, a rod to simultaneously move them, a stop on the carriage to move said rod at substantially the end of its forward travel to rotate the cam-fingers into the path to move the next work transversely of the carriage, substantially as described.

887,858. TYPE-CASTING MACHINE. JOHN W. LAMER, Chicago, Ill., assignor to August H. Weymann, Indianapolis, Wis. Filed Mar. 11, 1901. Serial No. 59,548. (No model.)

Claim.—A self-joint device, comprising a pair of complementary elongated rigid and anyhiding joint-plates provided with registering ball-balls, one of said plates being substantially smooth on its outer surface adjacent to said ball-balls and the other plate being provided on its outer surface with shoulders adjacent to said ball-balls, the shoulders being equidistant from the ball-balls and parallel with each other and extending the entire length of the plate, a screw-threaded bolt or bolt having an expanded head or heads adapted to be inserted through said pair of plates and through an interposed wall, and a nut or nut adapted to take said bolt or bolts therein and to fit between and bear against said parallel shoulders, whereby said bolt or bolts may be rotated in the nut or nuts which are held by the shoulders against turning while the inner surfaces of the head of the bolt or bolts bear against the smooth surface of the one-shouldered plate.

887,858. TYPE-CASTING MACHINE. JOHN W. LAMER, Berlin, Germany. Filed May 1, 1902. Serial No. 14,124. (No model.)

Claim.—1. In a machine for casting a type-bar from a previously-

composed line of matrices, the combination of a movable mold provided with a casting-chest, a carrier for the matrices normally movable with the mold, means for moving the mold and carrier together, and independent means for moving the carrier relative to the mold to change the position of the matrices transversely of the casting-chest, substantially as set forth.

2. In a machine for casting a type-bar from a previously-composed line of matrices, the combination of a carrier for the matrices, a casting-mold, the said mold and carrier being provided with teeth which mesh together whereby they are united, and means for moving the carrier and mold together from one position to another, substantially as set forth.

3. In a machine for casting a type-bar from a previously-composed line of matrices, the combination of a mold provided with a casting-chest, a carrier for the matrices, means for moving the carrier to bring them into casting position opposite the mold, other means for moving the carrier in order to adjust the matrices transversely relative to the casting-chest, means for connecting the carrier and the mold, and means for moving them together when connected, substantially as set forth.

4. In a machine for casting a type-bar from a previously-composed line of matrices, the combination of a carrier for the matrices of cylindrical form, a casting-mold connected with the said carrier whereby they move simultaneously, and means for moving the mold and the carrier into casting position, and from there to the position for discharging the bar of type and matrices, respectively, substantially as set forth.

5. In a machine for casting a type-bar from a previously-composed line of matrices, the combination of a carrier for the matrices of cylindrical form, a mold of hollow cylindrical form surrounding the said matrix-carrier, and means for moving the said carrier and mold to the casting position and to the discharge position, substantially as set forth.

6. In a machine for casting a type-bar from a previously-composed line of matrices, the combination of a carrier for the matrices of cylindrical form, a casting-mold of hollow cylindrical form surrounding the said casting-mold, the said carrier and mold being provided, respectively, with intermeshing projections whereby they are caused to move together, and means for moving them, substantially as set forth.

7. In a machine for casting a type-bar from a previously-arranged line of matrices, the combination of a carrier for the matrices of cylindrical form, means for imparting a rotary movement to the carrier, a casting-mold arranged concentrically to the carrier, and means for connecting the mold and carrier whereby they are caused to move together during portions of the rotation of the carrier, and whereby they may be separated or disconnected during other parts or portions of the rotation thereof, substantially as set forth.

8. In a machine for casting a type-bar from a previously-composed line of matrices, the combination of a carrier for the matrices of cylindrical form, a casting-mold of hollow cylindrical form surrounding the said carrier, the said parts being mounted concentrically relative to each other, and being provided with projections adapted to intermesh and hence cause the said parts to move together during part of their rotation, and being adapted to become disconnected when the parts are moved into certain positions, substantially as set forth.

9. In a machine for casting a type-bar, the combination of the matrices each provided on its face with a plurality of type impressions differing from the other, a carrier for the matrices, a casting-mold, means for connecting the mold and carrier whereby they move together, and means for adjusting the mold and carrier relative to each other whereby any one of the series of type impressions in the matrices may be brought opposite to the casting-opening in the mold, substantially as set forth.

10. In a machine for casting type-bars, the combination of a series of matrices each formed with a plurality of type impressions differing one from the other, a carrier for the said matrices, a casting-mold, a series of teeth or projections carried respectively by the mold and the carrier adapted to intermesh, whereby these parts are united and are caused to move together, and means for adjusting the mold and carrier relative to each

other whereby the different type impressions upon the matrices may be brought opposite the casting-opening in the mold, substantially as set forth.

11. In a machine for casting type-bars, the combination of a series of matrices, a carrier for the matrices, a casting-mold, means for tightly securing and holding the matrices in the carrier, means for uniting the mold and the carrier whereby they are caused to move together, and means whereby the carrier and mold may be adjusted relative to each other without distributing the matrices secured in the carrier, substantially as set forth.

12. In a machine for casting type-bars, the combination of a series of matrices, each provided with a plurality of type impressions differing one from the other, a carrier for the matrices of cylindrical form, a casting-mold of hollow cylindrical form surrounding the carrier and mounted eccentrically thereto, teeth or projections carried by the said carrier and mold adapted to intermesh and unite these parts, the teeth on one of the parts being interrupted whereby when moved into certain positions, the said parts are disconnected, means for moving one of said parts relative to the other one when thus disconnected in order to change the position of the matrices relative to the casting-opening in the mold, and means for moving the carrier and mold when connected, substantially as set forth.

13. In a machine for casting a bar of type, the combination of a series of the matrices adapted to be arranged in line with each other, each matrix having in its face a plurality of type impressions, a carrier for the matrices, a mold having a casting slot or opening adapted to be brought opposite the matrices, teeth carried respectively by the mold and the carrier and adapted to intermesh, the distance between adjacent teeth being equal to the distance between the different characters on a matrix, means for disconnecting the said teeth, and means whereby one of the said parts (the carrier and the mold) may be adjusted to change the relation of the intermeshing teeth whereby the position of the line of matrices relative to the casting-opening in the mold may be changed, substantially as set forth.

14. In a machine for casting a type-bar from a previously-arranged line of matrices, the combination with the line of matrices and the justifying device thereof, of a carrier for receiving and holding the line of matrices, and mold having a casting-opening, means for moving the carrier to bring the line of matrices opposite the casting-opening, a slide arranged to move the line of matrices close to the mold, another slide substantially parallel with the slide just referred to for operating the justifying device, and a single operating member for acting upon the said slides, substantially as set forth.

15. In a machine for casting a type-bar from a previously-arranged line of matrices, the combination with a line of matrices, a carrier therefor, a mold having a casting-opening, means for moving the carrier to bring the line of matrices opposite to the opening in the mold, and inclined or wedge-like devices arranged to act simultaneously upon opposite sides of the line of matrices to force it bodily toward the face of the mold, substantially as set forth.

16. In a machine for casting type-bars, the combination of a line of matrices, a carrier therefor, a mold provided with a casting-opening opposite to which the line of matrices is arranged, means for moving the mold and carrier simultaneously into casting position, and then for moving them simultaneously away therefrom, means for gradually moving the line of matrices toward the face of the mold as the parts approach the casting position and for gradually moving it away from the mold as they move from the casting position, and means for moving the line of type bodily against the face of the mold after the parts have come into casting position, substantially as set forth.

17. In a machine for casting type-bars, the combination of a cylindrical carrier for a line of matrices, a hollow cylindrical mold having a casting-opening opposite to which the line of matrices is arranged, the mold and carrier being mounted eccentrically relative to each other, and being so disposed that the line of matrices are brought close to the face of the mold when the parts are moved to molding position, and are gradually moved away from the face of the mold as the parts approach the position for discharging the cast bar of type and the line of matrices, substantially as set forth.

18. In a machine for casting type-bars, the combination of a line of matrices, the matrices being provided with inclined or cam-shaped surfaces, a carrier for the matrices, a mold having a casting-opening opposite to which the matrices are moved, a bar or slide arranged to be moved into engagement with the inclined surfaces of the matrices, and to thereby force them bodily toward and against the face of the mold, and means for moving the said bar or slide, substantially as set forth.

19. In a machine for casting type-bars, the combination of a line of matrices formed with inclined side edges, a carrier for the matrices, a mold having a casting-opening opposite to which the matrices are placed, a slide G1 adapted to engage with the inclined edges G3 of the matrices to force them bodily toward the face of the mold, and means for moving the slide, substantially as set forth.

20. In a machine for casting type-bars, the combination of a line of matrices, each provided upon its opposite edges with inclined surfaces

G2, G2, a carrier in which the matrices are placed, a mold having a casting-opening opposite to which the matrices are moved, two slides arranged upon opposite sides of the line of matrices and adapted to engage with the inclined surfaces G2 thereof, and means for moving the said slides into engagement with the matrices simultaneously, whereby the matrices are bodily moved toward the face of the mold, substantially as set forth.

21. In a machine for casting type-bars, the combination of a line of matrices, a carrier therefor of cylindrical form, a mold having a casting-opening opposite to which the matrices are moved, slides G1 mounted in the carrier for the matrices and arranged to engage with the matrices to force them toward and against the face of the mold, and means for moving the slides, substantially as set forth.

22. In a machine for casting type-bars, the combination of a series of matrices, a carrier therefor of cylindrical form, a mold, a pair of slides G1 mounted in the matrix-carrier and arranged to engage with the line of matrices and to move it bodily against the face of the mold, a slide G2 arranged to be moved between the ends of the slide G1 to move them into engagement with the matrices, and means for moving the slide G2, substantially as set forth.

23. In a machine for casting type-bars, the combination of a line of matrices, a carrier therefor, a mold, means for moving the line of matrices bodily toward and against the face of the mold, and springs for moving the line of matrices away from the face of the mold, substantially as set forth.

24. In a machine for casting type-bars, the combination of a line of matrices, a carrier therefor, a mold, means for moving the line of matrices into casting position and away therefrom, means for moving the line of matrices bodily toward and against the face of the mold when the parts are in casting position, and springs for moving the line of matrices away from the mold after the casting has been completed, substantially as set forth.

25. In a machine for casting type-bars, the combination of a line of matrices, a carrier having a cut or opening in which the line of matrices is arranged, a mold, means for moving the carrier so as to bring the line of matrices opposite the mold in casting position, means for moving the line of matrices bodily outward in its cut in the carrier toward the face of the mold, and springs arranged between the carrier and the matrices and tending to move the line of matrices inward in its cut, substantially as set forth.

26. A justifying device for use in a type-bar-casting machine consisting of three members arranged side by side, and having tail portions which are pivotally connected, and head portions arranged to be inserted between the type-matrices, the inner or middle member of the device being wedge shape and arranged to be moved between the outer members to crowd them apart, substantially as set forth.

27. In a machine for casting type-bars, the combination of a line of matrices, a carrier therefor of cylindrical form, a justifying device placed between certain of the matrices consisting of a plurality of members arranged side by side and having tail portions which extend to the axis of the carrier-cylinder, where they are pivotally united, the adjacent faces of the parts or members of the justifying device being inclined, whereby when the parts of the justifying device are moved into line with each other the line of matrices is justified, substantially as set forth.

28. In a machine for casting type-bars, the combination of a line of matrices, justifying devices, a carrier for the matrices and justifying devices, a mold, means for moving the carrier so as to bring the matrices into casting position, means for moving the line of matrices bodily toward the face of the mold, means for operating the justifying devices, the last said means being in operative relation only after the line of matrices has been bodily moved close to the mold, but being out of operative relation when the line of matrices is moved away from the face of the mold, substantially as set forth.

29. In a machine for casting type-bars, the combination of a line of matrices, justifying devices, a carrier for the matrices and justifying devices, a mold, means for moving the carrier to bring the matrices into casting position opposite the mold, slides which engage with the line of matrices and the justifying devices, and move them bodily toward the face of the mold and operate the justifying devices, and another slide which engages with and operates the justifying devices after the parts have been moved by the first-mentioned slides, to complete the justifying of the line, substantially as set forth.

30. In a machine for casting type-bars, the combination of a line of matrices, justifying devices, a carrier therefor, in the form of a hollow cylinder, a mold, slides G1, G1 arranged on the outside of the said cylindrical carrier which engage with the matrices and move them bodily toward the face of the mold, and also engage with the justifying devices and operate them, another slide G2 arranged on the inside of the said hollow cylindrical carrier and arranged to engage with and complete the movement of the justifying devices after the parts have been moved against the face of the mold, and means for operating the said slides, substantially as set forth.

31. In a machine for casting type-bars, the combination of a line of matrices, and justifying device, on elastic cap or casing 118 in which the said matrices and justifying device are arranged, and a carrier in which the cap or casing and the matrices and justifying device are mounted, substantially as set forth.

32. In a type-bar-casting machine, the combination of a carrier for the matrices, a gear having a continuous cycle of movement for driving the carrier, an intermittently-acting connection between the said gear and the carrier, whereby the latter is moved into the casting position and there allowed to rest, and is then moved to the discharging position for the cast line of type, substantially as set forth.

33. In a machine for casting type-bars, the combination of a carrier for the line of matrices, a gear for driving the carrier having a continuous cycle of movement, connecting means between the gear and carrier through which the gear moves the carrier, and means for disconnecting the carrier from the gear temporarily when it arrives at the casting position, whereby the carrier is given an intermittent motion without requiring the gear to stop in its movement, substantially as set forth.

34. In a machine for casting a bar of type and ejecting the same after casting operation, the combination of a carrier for a line of matrices adapted to move the matrices into the casting and the ejecting positions, a gear for driving the carrier, intermittently-acting connections between the gear and carrier, means for disconnecting such connections when the parts are in the casting position and the type-bar-ejecting position, and means independent of the gear for restoring the carrier to its initial position after the bar of type has been ejected, substantially as set forth.

35. In a machine for casting type-bars, the combination of a carrier for a line of matrices, a gear for driving the same, adapted to have a complete cycle movement, a continuously-rotating gear for giving motion to the carrier-driving gear, means under the control of the operator for starting the carrier-driving gear, and intermittently-operated connections between the said driving-gear and the carrier, whereby the latter is given an intermittent motion during the continuous cycle movement of its driving-gear, substantially as set forth.

36. In a machine of the class described, the combination of a part to be driven of cylindrical shape, a driving-gear therefor substantially concentric therewith, means for giving to the gear a continuous cycle of motion, a connecting-piece carried by the gear and adapted to engage with the part to be driven, and means for intermittently moving the said connecting-piece into and out of engagement with the part to be driven, whereby the latter is intermittently moved, substantially as set forth.

37. In a machine of the character described, the combination of a cylindrical member to be driven, a ring-shaped driving-gear concentric with a portion of the said cylindrical member, a catch 51 carried by the said ring-shaped gear and adapted to engage with the member to be driven, and a cam device for intermittently forcing the said catch into engagement with the body to be driven, substantially as set forth.

38. In a machine of the character described, the combination with a member to be driven having a cylindrical part such as the flange 2, a ring-shaped driving-gear concentric with the said flange, a catch-piece 51 carried by the said gear and adapted to engage with the said cylindrical flange, a stationary cam device 54 for moving the catch into engagement with the said flange, a spring tending to move it out of engagement therewith, and means for rotating the ring-like driving-gear, substantially as set forth.

39. In a machine for casting type-bars, the combination with a carrier for a line of matrices, molding devices for the cast bar of type, and the matrices, of a driving-gear for the carrier having a continuous cycle of movement, intermittently-operated connections between the said gear and the carrier, whereby the latter is brought to rest in the casting and ejecting positions, gearing for operating the casting devices arranged to be operated by the said driving-gear when the carrier is at rest in the molding position, and gearing for operating the ejecting devices, also driven by the said driving-gear arranged to operate when the carrier is at rest in the ejecting position, substantially as set forth.

40. In a type-bar-casting machine, the combination of a part to be driven having a cylindrical flange 2, a ring-like driving-gear 26 arranged concentric to the said flange, and provided with a set of internal teeth 45, cut away or interrupted as at 47, and with a set of external teeth 48, a driving-pinion 46 adapted to engage with the said teeth 45 and drive the gear 26, connections between the flange 2 and the gear 26, and casting and ejecting devices operated by the external gear-teeth 48, substantially as set forth.

41. In a type-bar-casting machine, the combination of matrices and justifying device, a carrier therefor, a driving-gear for the carrier having a continuous cycle of movement, connections between the gear and the carrier, means for intermittently disconnecting or breaking such connections, whereby the carrier is brought to rest in the casting position, mechanism for operating the justifying device, and gearing for the last said operating mechanism arranged to be put into motion by the said driving-

gear when the carrier comes to rest in the casting position, substantially as set forth.

42. In a machine for casting type-bars, the combination of a carrier for the matrices of cylindrical form, a driving-gear therefor, having a continuous cycle of movement, intermittently-operated connections between the driving-gear and the carrier, whereby the latter is intermittently moved, a sliding locking-bolt for locking the carrier when it comes to rest, and means operated by the said driving-gear for moving the said locking-bolt when the carrier is disconnected from the gear and comes to rest, substantially as set forth.

43. In a machine for casting type-bars, the combination with a carrier for the matrices, of a lock therefor, comprising a sliding bolt 107, a spring for forcing the said bolt in one direction, a controlling-bolt 108 for moving the sliding locking-bolt in the other direction, a driving-gear constituting part of the driving mechanism for the carrier having a continuous cycle of movement provided with raised and depressed portions with which a projection from the bolt 108 engages, whereby the latter is re-depressed, and intermittently-operated connecting means between the carrier and the said gear, substantially as set forth.

44. In a machine for casting type-bars, the combination with the molding device and the ejecting devices for the cast type-bar, of a cylindrical carrier for the matrices, a cylindrical mold having a casting-opening opposite to which the matrices are arranged, the mold and carrier being mounted concentrically relative to each other and so disposed that the surfaces of the mold and carrier are closest together when the parts are in casting position and are somewhat separated when they are in the ejecting position, substantially as set forth.

45. In a machine for casting type-bars, the combination of a carrier for the matrices, a mold in which the bar of type is cast, means for connecting the mold and the carrier, whereby they move together from the casting to the discharging position, a slide for forcing the matrices out of the carrier provided with a receiver for the cast type-bar; and means for forcing the cast type-bar out of the mold upon the receiver of the said slide, substantially as set forth.

46. In a machine for casting type-bars, the combination of a carrier for the matrices, a mold, means for moving the carrier and the mold away from the casting position, a sliding receiver for the bar of type provided with a pivoted bottom 98 adapted to constitute a chute or incline for discharging the type-bar, means for moving the said receiver, and means for forcing the cast bar-type out of the mold onto the said pivoted bottom of the receiver, substantially as set forth.

47. In a machine for casting type-bars, the combination of a carrier for the matrices, a mold having a casting-recess, means for moving the mold and the carrier from the casting position, a receiver for the cast bar of type arranged to be moved adjacent to the casting-recess in the mold, and having a pivoted swinging bottom, means for forcing the cast bar of type out of the mold and upon the said pivoted bottom of the receiver, means for moving the receiver, pins 100 with which the swinging bottom of the carrier engages when in position to receive the cast bar of type, and by which it is held up in line with the carrier, and stops or pins 101 with which the swinging bottom is adapted to engage when the receiver is withdrawn to discharge the bar of type, and by which the said bottom is held in an inclined position as to constitute a chute for the discharge of the type-bar, substantially as set forth.

48. In a machine for casting type-bars, the combination of a carrier for the matrices, a mold in which the type-bar is cast, a slide arranged to force the matrices out of the carrier and also to receive the cast type-bar, means for forcing the cast type-bar from the mold upon said slide, a lock for holding the slide in position while the type-bar is being forced out of the mold, and means for releasing the lock and for withdrawing the slide, substantially as set forth.

49. In a machine for casting type-bars, the combination of a cylindrical carrier having a recess for the line of matrices, a hollow cylindrical mold having a casting-recess opposite to which the line of matrices is arranged, means for connecting the mold and the carrier, whereby they move together, a sliding rack 75 adapted to be moved into the recess in the carrier and force therefrom the matrices after the casting has been effected, a wheel 74 having an interrupted toothed portion arranged to drive the said sliding rack, an ejector 98 arranged to enter the casting-recess in the mold and discharge therefrom the cast bar of type, a lever for operating the ejector, and a cam 89 for operating the lever, the cam being arranged on the same shaft with the wheel 74, and means for withdrawing the sliding rack, substantially as set forth.

50. In a machine for casting type-bars, the combination with the mold, the feet for containing the molten metal and means for forcing the metal from the feet to the mold, of a movable member having a series of openings through which the molten metal may be forced arranged between the feet and the mold, and means for moving and covering the same in different positions, whereby one or the other of the openings therein is brought into use, substantially as set forth.

51. In a machine for casting type-bars, the combination with the mold, the feed for containing the molten metal and means for forcing the metal from the feed to the mold, of a movable member arranged between the feed and the mold and provided with a series of openings through which the molten metal is forced to the mold, the said openings being of different sizes, and means for adjusting and securing the said member in different positions for bringing one or another of the said openings into use, substantially as set forth.

52. In a machine for casting type-bars, the combination of a mold having a plurality of casting-rooms of different sizes, a feed in which the molten metal is arranged, a feed member arranged between the feed and the mold provided with a plurality of openings of different sizes through which the molten metal is forced from the feed to the mold, and means whereby the mold and the said feeding member may be adjusted to bring the feeding-openings and casting-rooms of proper size opposite to each other, substantially as set forth.

53. The combination with a mold, a feed in which the molten metal is arranged and means for forcing the metal from the feed into the mold, of a pivoted feeding-coaster 13 arranged between the discharge-opening of the feed and the mold and provided with a series of openings 13 adapted to register with the casting-opening in the mold and the discharge-opening of the feed, and means for adjusting the said coaster so as to bring one or the other of its openings 13 into position for use, substantially as set forth.

54. In a machine for casting type-bars, the combination of a carrier for the matrices, a mold, means connecting these two parts whereby they are caused to move simultaneously, means whereby the parts may be disconnected, and means for moving one of these parts relative to the other when they are disconnected whereby their relative position may be changed, substantially as set forth.

55. In a machine for casting type-bars, the combination of a carrier having a recess adapted to receive a line of matrices, a mold having a casting-room, means for uniting the mold and carrier whereby they move together, automatic means for moving the mold and carrier into and away from the casting position, means under the control of the operator for disconnecting the mold and carrier, and for changing the relative position of the mold and carrier and then connecting them, substantially as set forth.

56. In a machine for casting type-bars, the combination of a carrier for the line of matrices of cylindrical form, a hollow cylindrical mold having a casting-opening opposite to which the line of matrices is arranged, means for uniting the mold and carrier whereby under normal conditions they move together, means under the control of the operator for disconnecting the mold and the carrier, and means for changing the relative positions of the mold and carrier, substantially as set forth.

57. In a machine for casting type-bars, the combination of a carrier for a line of matrices of cylindrical form and arranged to turn about its axis, a hollow cylindrical mold arranged outside of the carrier and mounted to turn on its axis, the mold and the carrier being concentric to each other, interlocking projections carried by the mold and carrier, respectively, arranged to unite these parts and cause them to move together under normal conditions of operation and also arranged to separate, by reason of the offset concentric mounting of the parts when moved into an unusual position, means under the control of the operator for moving the mold and carrier into an unusual position to disconnect their interlocking projections, and means whereby one of the parts may be partly turned relative to the other to change their angular relation, substantially as set forth.

58. In a machine for casting type-bars, the combination of a cylindrical carrier for the line of matrices, a cylindrical mold, the carrier and mold being provided, respectively, with gear-teeth, means for normally connecting the carrier and mold, means whereby they may be at the will of the operator disconnected, gear-wheels meshing with the said gear-teeth of the mold and carrier, means for uniting the said gear-wheels whereby they move together, and means for moving one of the wheels without moving the other, whereby the angular relations of the carrier and mold may be varied, substantially as set forth.

59. In a machine for casting type-bars, the combination of a cylindrical carrier for a line of matrices arranged to be turned about its axis, a cylindrical mold arranged to be turned about its axis, means for connecting the mold and carrier under normal conditions of operation whereby they are caused to move together, adjusting-gear under the control of the operator arranged to be brought into engagement with the said mold and carrier to change their angular relations, and means for holding the said adjusting-gear out of engagement with the mold and carrier under normal conditions of operation, substantially as set forth.

60. In a machine for casting type-bars, the combination of the carrier for the matrices of cylindrical form, a hollow cylindrical mold surrounding the carrier, the said mold and carrier being provided with toothed flanges, means for connecting the carrier and mold under normal conditions

whereby they will move together, gear-wheels 124 and 126 arranged to mesh with the toothed flanges of the carrier and mold, respectively, a shaft and sleeve upon which the said gear-wheels are respectively mounted, means for connecting the shaft and sleeve whereby they are caused to turn together and means for disconnecting them whereby one may be moved independently of the other to move either the mold or the carrier without a corresponding movement of the other part, substantially as set forth.

61. In a machine for casting type-bars, the combination of a carrier for the matrices, a mold, a gear having a continuous cycle movement for moving the parts into positions for casting, and for discharging the cast type-bar and the matrices, intermittently-operated connecting means between the said gear and the carrier and mold whereby the latter are brought to rest at the casting and the discharging positions respectively, and a weight for restoring the carrier and mold to their initial positions after the discharging of the type-bar and the matrices has been effected, substantially as set forth.

697,860. PLACKET-CLOSURE. LAWRENCE W. LORIAN, Chicago, Ill. Filed Sept. 20, 1901. Serial No. 78,141. (No model.)

Claim.—1. A placket-closure comprising two flexible members finally secured together at one end and adapted to be attached to opposite edges of the placket, these members being normally curved in opposite directions.

2. A placket-closure comprising two flexible members finally secured together at one end and adapted to be attached to opposite edges of the placket, one of these members being of a form substantially similar to that carried in use and the other being curved in the opposite direction.

697,861. MECHANICAL CALCULATOR. WILLIAM H. MAC-CHILL, Philadelphia, Pa., assignor to the Western-Union Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Jan. 7, 1902. Serial No. 26,771. (No model.)

Claim.—1. A calculating device comprising a chart of cubical form having a series of spaces, certain dimensions marked within said spaces, lines adjacent to, but beyond the spaces containing the dimensions, each line being divided into parts of equal length, a division-line for the dimensions marked within the spaces of the chart, the said dimensions differing in character on either side of said division-line, and a pointer suitably mounted with relation to the chart, one of said members being movable with respect to the other, said pointer having an opening equal to one row of spaces and having also a series of numbers disposed on either side of said slot, which numbers are to be read when the end of the

pointer is opposite one of the markings of the outer line, in connection with the numbers viewed through said opening, the numbers on one side of said dial being read in connection with the dimensions on one side of the dividing-line, and vice versa.

2. A calculating device consisting of a disk having a series of spaces formed by radial and concentric lines having a common center, certain dimensions marked in said spaces, outer concentric circles divided into a series of spaces of equal length, a dividing-line for the dimensions marked within the spaces of the disk, the said dimensions differing in character on either side of said dividing-line, and a pointer mounted at the center of the disk or disk, one of said members being movable with respect to the other, said pointer having a dot overlying the series of dimensions marked within the concentric spaces, and having also a series of numbers disposed on either side of said dot, which numbers are to be read, when the end of the pointer is opposite one of the markings of the outer circle, in connection with the numbers viewed through said dot, the numbers on the left-hand side of said dot being read in connection with the dimensions in the spaces to the right of the dividing-line, and vice versa.

3. A calculating device having a series of spaces with dimensions therein representing "stair-cases," another series of spaces with dimensions therein representing "stair-treads," marks arranged beyond said spaces to indicate heights between floors, and a dotted pointer carrying certain figures indicating the number of steps, the dimensions of "rises" and "treads" being viewed through the dot of the pointer when the end of the same is brought opposite one of the marks indicating the height between floors.

697,869. SHIELD ATTACHMENT FOR GUN. JOHN F. HARR, Bethlehem, Pa., assignor to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Nov. 4, 1904. Serial No. 51,697. (No model.)

Claim.—1. The combination of the gun-shield consisting of two shield-sections having their front edges beveled to fit together at an angle, a gun-support having a V-shaped extension fitting into the angular portion of the shield, means for securing the shield to said extension, and yielding side supports for the shield-sections, substantially as described.

2. The combination with a gun, of a V-shaped shield centrally supported on the gun, with its apex above and below and on a line extending through the axis of the gun, and yielding side supports for the shield, substantially as described.

3. A gun-shield formed of two shield-sections of armor-plate meeting above and below the gun on a line extending vertically through the axis thereof, a support for the forward portion of the shield, and side supporting-springs, substantially as described.

4. A gun-shield consisting of two shield-sections meeting and secured together at their front edges along a vertical line and at an angle to each other, combined with a gun-cleave, and a V-shaped extension connected with said gun-cleave at its forward end, and secured to and supporting said shield-sections, with a gun-part in the front end of each shield-section, substantially as described.

5. The combination of two shield-sections of armor-plate, with the front edges beveled to fit together at an angle, a gun-cleave having a V-shaped extension at its front end fitting within the front end of each shield, means to secure each shield to said extension, and supporting-springs secured to said gun-cleave and to said shield-sections, substantially as described.

6. The combination of shield-sections of armor-plate, each being bent about a vertical line near the center of the same and the front edges meeting and beveled to fit together, a gun-cleave to support a gun, an extension formed on said gun-cleave and secured to said shield-sections, and curved laminated springs secured to said shield-sections and to said gun-cleave, substantially as described.

7. The combination of two shield-sections of armor-plate, meeting at an angle and having a gun-part in the front and provided with a sight-hole, a gun-cleave, a shield-supporting extension secured to said gun-cleave,

means to secure said shield-sections to said extension, and side supporting-springs, substantially as described.

8. The combination of two shield-sections of armor-plate, meeting at an angle, a gun-cleave having a V-shaped extension at its front end fitting within the angle formed by the shield-sections, and means to secure each shield-section to said extension, substantially as described.

9. The combination with a gun, of a V-shaped shield with its apex on a line extending vertically through the axis of the gun and having a part for the gun in the angular portion, and means for supporting the shield to swing with the gun, substantially as described.

10. The combination with a gun, of a V-shaped shield having its apex in a line extending vertically through the axis of the gun and provided with a gun-part in its angular portion, and means for supporting the shield to move in all directions with the gun, substantially as described.

697,868. ONE-ROASTING FURNACE. THOMAS B. KERR, Spotswood, Victoria, Australia. Filed Dec. 21, 1900. Serial No. 41,601. (No model.)

Claim.—In an one-roasting furnace, a plurality of superposed communicating hearths, a series of hollow vertical shafts passing through the hearths, a water-supply pipe having a series of depending branches corresponding in number with and located in the respective shafts, a driving-shaft common to all and operatively connected with said shafts, arms extending radially from said shafts, means for connecting the arms rigidly yet removably to said shafts, bars connected to said arms, rubbing-rolls detachably depending from said bars, notched lugs extending from said arms, and stay-rolls connected to said bars and having eyes to engage the notched lugs.

697,864. JOURNAL-BEARING. IRVING HERRMAN, Winfield, Iowa. Filed Sept. 1, 1900. Serial No. 22,177. (No model.)

Claim.—1. In a journal-bearing, the combination of a spindle; a box having an enlarged oil-chamber and two points of bearing against said spindle; and a collar secured to said spindle between said points of bearing; substantially as set forth.

2. In a journal-bearing, the combination of a spindle; a box constructed around said spindle at one point and having an enlarged oil-chamber surrounding said spindle at another point; a collar secured to said spindle and abutting against said construction; and a bushing threaded in said box and abutting against said collar; substantially as set forth.

3. In a journal-bearing, the combination of a spindle; a box constructed around said spindle at one point and having an enlarged oil-cavity surrounding said spindle at another point; a collar detachably secured to said spindle and abutting against said construction, and also bearing at its periphery against said box; and a bushing threaded in said box and abutting against said collar; substantially as set forth.

4. In a journal-bearing, the combination of a spindle having the shoulder 8; a collar secured on said spindle at a distance from said shoulder; a bushing secured between said shoulder and collar; a box inserted over said spindle and collar and threaded on said bushing and having a construction abutting against the end of said collar remote from said bushing, the outer end of said box being closed around the end of said spindle and having an oil-cavity surrounding said spindle; substantially as described.

5. In a journal-bearing, the combination of a spindle having the shoulder 8; a collar secured on said spindle at a distance from said shoulder; a bushing located on said spindle between said shoulder and collar; a box closed at its outer end and inserted over said spindle and collar and threaded on said bushing; a hub inserted over said box; the flange 11 on said bushing abutting against the inner end of said hub; and a screw-plug in the outer end of said box, having an enlarged flange 13 also overlapping and abutting against the outer end of said hub; substantially as set forth.

697,865. ELLIPTICAL SPRING. CHARLES A. MILLER, Marshalltown, Iowa. Filed Dec. 18, 1901. Serial No. 61,338. (No model.)

Claim.—1. A leaf for an elliptical spring, which leaf is formed of bar metal and has a stud stamped in its center and portions struck up on either side of and spaced apart from said stud and extending laterally to the long margins of the leaf.

2. A leaf or plate for an elliptical spring, having struck-up portions in the centers of its long edges and a central stud or stud between said struck-up portions.

3. The combination of a saddle formed with a seat in its upper face, the plurality of spring-leaves, each formed with a central depressed seat and struck-up angular portions in the centers of its long edges, conforming to and nesting with each other successively, the lowermost leaf conforming to and nesting in the seat of its support, together with counter-part band members shaped to embrace the several leaves jointly and also shaped to conform to the upper and lower faces of the collection of leaves and to the upper face of the saddle, in which band members the spring-leaves are mounted loosely.

697,866. NEEDLE-HOLDER. ROBERT MILLER, Cortland, N. Y. Filed Dec. 8, 1901. Serial No. 64,730. (No model.)

Claim.—1. A toilet article embodying a Shank hollow at one end and forming a needle-eye in said end, a plurality of disks spaced and secured on the hollow portion of the Shank, thus providing thread-spools integral therewith; and a thumb-like casing removably secured on the disk furthest from the hollow end, thus affording a cover for the open end of the case and for the spool.

2. A toilet article, embodying a Shank hollow at one end, disks secured at intervals upon the hollow portion of the Shank, one disk having its edge screw-threaded, and a thumb-like casing adapted to screw upon the threaded edge of the disk.

697,867. GAS-PRODUCER. LOUIS W. HARR, Regents Park, London, England. Filed Nov. 15, 1901. Serial No. 52,756. (No model.)

Claim.—In combination with a cylindrical gas-producer having at the top a bell containing raw fuel and at the bottom a grate in the form of an inverted truncated cone, a central hollow retentive shaft carrying agitating-arms, having at the top of the bell lateral inlets for gases and vapors, a steam-injector within it, and having at its lower end outlets for gases and vapors into the mass of incandescent fuel, substantially as and for the purpose set forth.

697,867.

697,868. TRAIN-SIGNAL LAMP. EDWARD F. MOORE, Hobart, Mo., and JOHN LAMER, Littlefield, Ill. Filed Sept. 2, 1901. Serial No. 74,332. (No model.)

Claim.—1. In a lantern, a casing having conical projections, a cylinder therein having horizontal and vertical intersecting slots, webs, one of which is slotted, connecting the casing and cylinder and forming a way, an inner cylinder having openings registering with the conical projections, racks thereon, transparent plates of varying colors in the racks, a rod having an end projecting through the slot of the first-named cylinder and joined to the inner cylinder and means for holding the rod elevated.

2. In a lantern, a casing having conical projections, a cylinder therein having horizontal and vertical intersecting slots, webs, one of which is slotted, connecting the casing and cylinder and forming a way, an inner cylinder having openings registering with the conical projections, racks thereon, transparent plates of varying colors in the racks, a rod having an end projecting through the slot of the first-named cylinder and joined to the inner cylinder, a sliding plate, a guide thereon for the rod and means for holding the rod elevated substantially as described.

697,869. GLOVE-FASTENING. WILLIAM E. MURPHY, New York, N. Y. Filed July 2, 1901. Serial No. 66,369. (No model.)

Claim.—1. In a fastener for gloves and similar articles, a circular spring coact member constructed with two or more parallel slots or cuts, substantially as described.

2. In a fastener for gloves and similar articles, a circular coact member divided into four or more sections by means of parallel slots or cuts, substantially as described.

3. In a fastener for gloves and similar articles, a socket member divided into four or more sections by means of parallel slots or cuts, two of said sections being larger segments of circles than the others, substantially as described.

4. In a fastener for gloves and similar articles, a circular socket member constructed with two or more parallel slots or cuts, and means for securing the socket member to the glove or other article, substantially as described.

5. In a fastener for gloves and similar articles, the combination with a stud, of a socket constructed with two or more parallel slots or cuts adapted to receive said stud, substantially as described.

6. A socket for a glove-fastener having a stud-receiving opening, an annular part or projection surrounding said opening, divided into four or more sections by means of parallel slots or cuts, two of said sections being comparatively wide and stiff and the others comparatively narrow and yielding, substantially as described.

7. A socket for a glove-fastener formed with a stud-receiving portion, the edges of which are turned and folded back upon themselves, parallel slots being arranged in said edges and in the walls of the socket comparatively close together so as to form wide comparatively stiff portions and intermediate yielding or resilient portions, the intermediate yielding portions facilitating the inserting of a stud into the socket, while the stiff portions enable the socket to grip the stud efficiently to retain the same, substantially as described.

8. A socket for a glove-fastener comprising a stud-receiving portion having approximately cylindrical walls, the outer edges of said walls being made yielding by slots arranged parallel with each other and comparatively close together, whereby two sections of the walls will be wide and comparatively stiff while the other two sections will be quite narrow and yielding or resilient and means for holding the socket-walls in position on the glove or other article, substantially as described.

697,870. **WY-LOCK.** HENRIETTA McDONALD, Fitch, Canada, assignor of one-half to ALVIN J. CRIG, Fitch, Canada. Filed June 14 1901. Serial No. 64,364. (No model.)

Claim.—A wy-lock, comprising a plate having openings for receiving nuts of bolts for securing fish-plates to rails, and also having perforations near the ends, and locking-clips of plate-like construction arranged between the locking-plate and the fish-plate and through which securing-bolts pass, the said clips being of sufficient width to engage their edges against the head and base flange of the rail, and tongs on said clips for passing through the perforations at the ends of the locking-plate, substantially as specified.

697,871. **CURVED-HAT-SWAY-FLANGING MACHINE.** ARTHUR E. HILLMAN and FREDERICK BARNES, Brooklyn, N. Y., assignors to CANTARUS HESS, Brooklyn, N. Y. Filed Dec. 12, 1901. Serial No. 66,981. (No model.)

Claim.—1. A flanging-machine, comprising a pair of revoluble dies, and a guide-plate at the entrance side of the dies for guiding the edge of

an article to the dies, the said guide-plate having an upturned and overhanging flange forming a tapering guideway with outwardly-flaring mouth to guide the article to the dies and to assist in turning over the edge of the blank sufficiently for the revoluble dies to complete the crimping, the bottom of the guide-plate being arched to accommodate tubular articles of different diameters, as set forth.

2. A flanging-machine, comprising a pair of revoluble dies, a guide-plate at the entrance side of the dies for guiding the edge of an article to the dies, the said guide-plate having a segmental body portion and an upturned and overhanging flange forming a tapering guideway with outwardly-flaring mouth to guide the article to the dies and to assist in turning over the edge of the blank sufficiently for the revoluble dies to complete the crimping, and means for adjusting the guide-plate relatively to the said dies, as set forth.

3. A flanging-machine, comprising a pair of revoluble dies located one above the other, a guide-plate at the entrance of the said dies for guiding the edge of an article to the dies, shafts carrying the revoluble dies and geared together, bearings for the said shafts, one of the bearings for the upper shaft being telescoped and the other bearing mounted to slide, springs arranged on opposite sides of the sliding bearing and means for compressing one of the springs, as set forth.

4. A flanging-machine, comprising a pair of revoluble dies located one above the other, a guide-plate at the entrance of the said dies for guiding the edge of an article to the dies, shafts carrying the revoluble dies and geared together, bearings for the said shafts, one of the bearings for the upper shaft being telescoped and the other bearing mounted to slide, springs arranged on opposite sides of the sliding bearing, and a cam-lever for compressing the spring on one side of the sliding bearing to lock the said bearing against the tension of the spring on the other side of the bearing, as set forth.

5. A flanging-machine, comprising a pair of revoluble dies having annular registering bevels and annular registering grooves adjacent to the bevels and half-round in cross-section, the grooves being adjacent to the inner faces of the dies and the bevel of one inclining downwardly and outwardly from the groove and the bevel of the other inclining upwardly and outwardly from the groove and a guide-plate at the entrance side of the dies for guiding an article to the same, as set forth.

6. A flanging-machine, comprising a pair of revoluble dies having annular registering bevels and annular registering grooves adjacent to the bevels and half-round in cross-section, the grooves being adjacent to the inner faces of the dies and the bevel of one inclining downwardly and outwardly from the groove and the bevel of the other inclining upwardly and outwardly from the groove and a guide-plate at the entrance side of the dies for guiding an article to the same, the said guide-plate having a curved bottom and an upwardly-turned flange forming a tapering guideway with outwardly-flaring mouth, as set forth.

7. In a flanging-machine, a pair of revoluble dies having annular registering bevels and grooves adjacent to the inner faces, the bevel of one die inclining downwardly and outwardly from the groove and the bevel of the other inclining upwardly and outwardly from the groove, as set forth.

697,872. **FRAME.** SAMUEL GLASSMAN, Hoboken, N. J., assignor to KRONHEIMER & GLASSMAN, Company, a Corporation of New York. Filed Dec. 20, 1901. Serial No. 67,714. (No model.)

Claim.—1. In a device of the character described, the combination of a sheet-metal frame member *a*, the rear edges of the sides of which are bent inwardly and a back *b*, provided with bent-over edges, substantially as shown and described.

2. In a device of the character described, the combination of a sheet-metal frame member the front and rear edges of the sides of which are bent inwardly, the rear edges being also bent toward the center at points intermediate of the corners, and a back, substantially as shown and described.

3. In a device of the character described, the combination of a sheet-metal frame member, the front and rear edges of which are bent inwardly, the rear edges being also bent toward the center at points intermediate of the corners and a back member provided with converging bent-over edges, substantially as shown and described.

697,878. LADY'S BELT. EDWARD CLAMMERTON, Hoboken, N. J., assignor to Krumboltz & Oldenbush Company, a Corporation of New York. Filed Jan. 16, 1902. Serial No. 89,894. (No model.)

Claim.—1. In a device of the character described, a back bar provided with an eyelet near the lower end thereof, a belt threaded through such eyelet, an eyelet near the upper end of the back bar, and having a belt therein, and means for connecting the free ends of the belt, substantially as shown and described.

2. In a device of the character described, a back bar provided with three eyelets, one of such eyelets being placed near the lower end of such back bar and two of such eyelets being placed near the upper end of such back bar, a belt in the lower eyelet and another belt in the upper eyelet and means for holding together the free ends of the said belt, substantially as shown and described.

3. In a device of the character described, a back bar provided with an eyelet *A*, a belt *f* therein, a secondary belt *e* above the belt *f*, means for holding the belt *e* and *f* apart at the back of the wearer, and means for connecting the ends of the belt, substantially as shown and described.

697,874. CONVEYER. JOSEPH OLSEN, Brooklyn, N. Y. Filed Apr. 2, 1901. Serial No. 85,957. (No model.)

Claim.—The combination of a belt of sheet metal having notches or recesses in its lateral edges, and carrying buckets upon its outer surface, and the pairs of spaced-apart disks each pair being secured upon a common shaft and having peripheral teeth engaging said notches of said belt, substantially as set forth.

697,875. ROTARY CUTTER. FRIEDRICH FARM, Essen, Germany, assignor to Fried. Krupp, Essen, Germany. Filed Jan. 11, 1902. Serial No. 89,893. (No model.)

Claim.—1. A rotary cutter having its surface divided by oblique channels into cutting-sections, and each cutting-section being grooved to form a large number of inwardly-curved ridges of approximately triangular or outwardly-tapering section, forming at their intersection with the channels, cutting-teeth offset in one section with respect to those in a neighboring section.

2. A rotary cutter comprising a cylindrical body, cut with oblique channels dividing it into sections and intersecting circumferential spiral

grooves of profile forming inwardly-curved ridges of outwardly-tapering cross-section; the intersection of said ridges with the channels forming outwardly-tapered cutting-teeth.

697,876. HEATING AND COOKING STOVE. JAMES C. PARKER, New Britain, Mo. Filed Sept. 26, 1901. Serial No. 78,672. (No model.)

Claim.—1. In a stove, the combination with the combustion-chamber, of air-fuel tubes projecting through the top of the stove vertically into said chamber in the path of the flames and escaping products of combustion and provided with horizontal discharge branches extending through the fuel-space of the combustion-chamber and over the bottom of the latter, the upper ends of said fuel-tubes being in communication with the atmosphere, substantially as described.

2. In a stove, the combination with the combustion-chamber, of air-fuel tubes projecting vertically into said chamber through the top of the stove and provided with horizontal discharge branches extending through the fuel-space of the combustion-chamber and over the bottom of the latter, whereby the air fed by said tubes is heated before it is discharged into the chamber, a tube extending through the top of the stove and projecting into the combustion-chamber, the said tube operating to feed air at the temperature of the atmosphere into the combustion-chamber in proximity to the discharge ends of the hot-air-fuel tubes, and means for regulating the passage of the air through the said pendant tube, substantially as described.

3. In a stove, the combination with the combustion-chamber of air-fuel tubes projecting vertically into said chamber through the top of the stove and provided with horizontal discharge branches extending through the fuel-space of the combustion-chamber and over the bottom of the latter, the upper end of said fuel-tubes being in communication with the atmosphere and a circulation line for conducting the heated air and products of combustion from said chamber to and over the bottom of the stove and underneath said combustion-chamber said line operating to cause the heated air and products of combustion to pass in a direction opposite to which the heated air passes through the horizontal branches of said fuel-tubes, substantially as described.

4. In a stove, the combination with the combustion-chamber, of an air-fuel tube projecting into said chamber through the top of the stove and provided with a draft-regulator, a circulation line for conducting the heated air and products of combustion from said chamber to and over the bottom of the stove and beneath the combustion-chamber, and means for introducing heated air through the fuel into the combustion-chamber near the discharge end of the air-fuel tube, substantially as described.

5. In a stove, the combination with the combustion-chamber, of an air-fuel tube projecting into said chamber through the top of the stove, said stove-top being provided with a fuel-fuel aperture, an oscillating cover for closing said aperture, and means automatically thrown into operation by the oscillating opening movement of said cover for closing the air-fuel tube, substantially as described.

6. In a stove, the combination with the combustion-chamber, of an air-fuel tube projecting into said chamber through the top of the stove, said stove-top being provided with a fuel-fuel aperture, an oscillating cover for closing said aperture, means automatically thrown into operation by

the oscillating opening movement of said cover for closing the air-fed tube, and a draft-regulator for controlling said air-fed tube, substantially as described.

7. In a stove, the combination with the combustion-chamber and means for feeding atmospheric air thereto, of air-tubes leading from the exterior of the stove to and through the combustion-chamber in the path of the flames and escaping products of combustion and over the bottom of said chamber and arranged to deliver heated air into the latter, and a circuitous flue for conducting the heated air and products of combustion from said chamber to and over the bottom of the stove and beneath the combustion-chamber, substantially as described.

8. In a stove, the combination with the combustion-chamber and means for feeding atmospheric air thereto, of air-tubes arranged in the interior of the combustion-chamber, each of said air-tubes being bent at an angle and communicating at its upper end with the atmosphere through the top of the stove and arranged at its lower end horizontally over the bottom of the combustion-chamber to deliver heated air into the said chamber, the pendant portion of said tubes being arranged in the path of the flames and escaping products of combustion, and a circuitous flue for conducting the heated air and products of combustion from the combustion-chamber to and over the bottom of the stove and beneath the said chamber, substantially as described.

697,877. WRENCH. JOHN E. PARSONS, Gering, Neb. Filed Aug. 7, 1904. Serial No. 71,232. (No model.)

Claim.—1. The combination, with a wrench-jaw provided with an operating-spindle; and a plate in which the said spindle is journaled said plate having two bearings for engaging the wheel-rim arranged one on each side of the said spindle and having also a bar which projects across the wheel-rim between the said bearings; of a clamping-lever pivoted against the front side of the said bar overwise and to one side of the axis of the said spindle and working in a plate which is overwise of the two said bearings, said lever having a bearing edge arranged longitudinally of it, substantially as set forth.

2. The combination, with a wrench-jaw provided with an operating-spindle; and a plate in which the said spindle is journaled said plate having two bearings for engaging the wheel-rim arranged one on each side of the said spindle and having also a bar which projects across the wheel-rim between the said bearings and has a pivot-pin projecting from the front side of its free end portion overwise and to one side of the axis of the said spindle; of a clamping-lever pivoted on the said pivot-pin and working in a plate overwise of the said bearings, said lever having a bearing edge arranged longitudinally of it, substantially as set forth.

697,878. NON-REFILLABLE BOTTLE. JAMES Y. PATTON, Wal-
dron, Ark. assignor of one-half to Gordon Cox, Waldron, Ark. Filed
Aug. 17, 1904. Serial No. 72,577. (No model.)

Claim.—1. A non-refillable bottle comprising the bottle-neck having a bottom wall provided with a filling-part, port, the neck of the bottle being provided diametrically opposite the filling-part with the discharge-part and with a tubular portion forming a continuation of said part and terminating below the upper end of the neck of the bottle, each bottle-neck being provided internally near its upper end with a groove having a stop-shoulder for engagement by a detent, the longitudinal rib within the bottle-neck and terminating at its ends short of the upper and lower ends of the neck, the cap-stopper fitted to the bottle-neck and having said detent operating in the groove of the bottle-neck and a lateral flange provided in its under side with a groove to receive the end of the bottle-neck, each flange being arranged to overlap the outer end of the outlet-part and having a notch which may be set into register with each end of the part, the plunger having a shank portion movable longitudinally in the cap-stopper and hinged thereto, whereby it can only turn with the said stopper, said plunger being provided with a piston having a longitudinally-extended rib and opposite the same a tooth or spur occupying a position above the upper end of the said rib, and the dispensing-cylinder fitted within the bottle-neck snugly below the rib therein and having a slot which may be entered by the rib of the plunger-piston, a chamber in which said piston may operate and being movable by the operation of the plunger to adjust said slot into register with the filling and discharge parts of the bottle-neck, substantially as and for the purpose set forth.

2. A non-refillable bottle comprising the bottle-neck having a filling-part and a discharge part, a dispensing-cylinder having a side slot which may be adjusted to register with one or the other of said parts, and means for operating the said cylinder to cause its slot to register with one or the other of said parts, substantially as set forth.

3. A non-refillable bottle having a bottle-neck provided with a filling-part and a discharge-part, a dispensing-cylinder having a slot through which it may be filled and discharged, and means for operating the dispensing-cylinder including a piston to occupy the chamber thereof in re-adjusting the cylinder from discharging to filling position, substantially as set forth.

4. The combination of the bottle-neck having a filling-part and a discharge-part, the dispensing-cylinder having a slot which may be turned to register with either of said parts, and will when registered with one part, operate to close the other part, and means for operating the cylinder, substantially as set forth.

5. The combination of the bottle-neck, the dispensing-cylinder arranged to rotate therein, and the plunger having piston movable into the said cylinder and arranged to rotate within the bottle-neck, and the plunger rotating with and movable longitudinally independently of the cylinder, said cylinder being formed to cooperate with the said parts in the bottle-neck, substantially as set forth.

6. A bottle having filling and outlet parts, combined with a dispensing-cylinder having a chamber and a port leading thereto, which port may be adjusted to register with the filling or outlet part of the bottle, and means for occupying the chamber of the dispensing-cylinder in the readjustment of said port from register with the outlet-part to its registry with the filling-part whereby to exclude liquid from said chamber during each operation, substantially as set forth.

7. The combination of a bottle having a filling-part and a discharge-part, a dispensing device having a chamber and a port leading thereto through which the chamber may be filled from the filling-part, and emptied from the discharge-part, and a piston movable into the dispensing device in the readjustment thereof from registration with the outlet-part to its registration with the filling-part, whereby to secure the discharge of any material within the dispensing device before each device is adjusted into registry with the filling-part, substantially as set forth.

8. A bottle having its neck provided with a bottom wall having a filling-part and provided alongside said neck with a tubular portion communicating at its lower end with the neck and affording an outlet or discharge part, and a rotatable dispensing device in the neck above the bottom wall and having a slot or opening which may be adjusted by the turning of the dispensing device, successively into register with the inlet and outlet parts substantially as set forth.

9. A bottle having inlet and outlet parts provided within its neck with a longitudinally-extended rib which may limit the turning movement of a device inserted in the neck of the bottle, and a rotatable dispensing device controlling said inlet and outlet parts operating in the neck and cooperating with said rib, substantially as set forth.

10. The combination of the bottle-neck having filling and discharge parts, the cylinder in said neck and movable between positions in which it will register with one or the other of said filling and discharge parts, and a piston adapted to fill said cylinder and exclude liquid therefrom and movable into and out of position in which it will fill said cylinder substantially as set forth.

11. The combination in a bottle of the neck having the longitudinal

rib and provided with the filling and outlet ports, the dispensing-cylinder operating below said rib and having a slot which may be adjusted into registry with the filling-port, and with the outlet-port, the plunger having a piston movable longitudinally in the dispensing-cylinder and provided with a rib to operate in the slot of the dispensing-cylinder, said plunger being movable longitudinally independent of the cylinder and rotatable with said cylinder, and means whereby to prevent the reverse movement of the plunger, and confine its turning movements to one direction, substantially as set forth.

12. The combination of the bottle-neck having a filling-port and an outlet-port, the cap-stopper held in the bottle-neck and arranged to turn therein, means limiting the turning movement of the cap-stopper to one direction, a longitudinal rib within the neck of the bottle, the dispensing-cylinder operating in the bottle-neck below the said rib and having at one side a slot through which it may be filled and emptied, the plunger having a shank keyed to and movable longitudinally in the cap-stopper, and a piston movable within the dispensing-cylinder and provided with a rib operating in the slot thereof, substantially as set forth.

13. The combination of the bottle-neck, provided within it near its upper end with an annular groove, and the ratchet-teeth in the base-wall of said groove, the cap-stopper having a portion fitted within the neck of the bottle and provided with an annular groove and with a socket leading therefrom, and the detent having its end portion fitting in said socket and a projecting portion which may be pressed into the groove of the cap-stopper or may spring outward into the groove of the bottle-neck, substantially as set forth.

14. A bottle having its neck provided with a bottom wall having a filling-port and said neck also provided with a lateral outlet-port and a dispensing device having a port which may be registered alternately with the filling and discharge ports of the bottle-neck, and means for operating the dispensing device to adjust its port into register with one or the other of the bottle-ports, substantially as set forth.

15. The combination with the bottle-neck having the internal longitudinal rib and the dispensing-cylinder having a side slot, of the plunger having a piston fitted to the dispensing-cylinder and provided with a rib and with a tooth or spur for engagement with the rib of the bottle-neck, the bottle being provided with filling and outlet ports with which the said side slot may be registered, substantially as set forth.

16. The combination with the bottle-neck, and a dispensing-cylinder operating therein, of the plunger arranged to operate such cylinder and having a portion arranged and adapted to fill the cylinder when the latter is being adjusted to its filling position, the bottle-neck and cylinder having cooperating ports, substantially as set forth.

17. The combination of the bottle-neck having a filling-port and a discharge-port, and an internal rib, a cap-stopper provided with means whereby it may be held in the bottle-neck and for limiting the turning movement thereof to one direction, the dispensing-cylinder having a slot through which it may be filled and emptied and arranged to turn within the bottle-neck beneath the rib thereof, and the plunger having a shank keyed to and movable longitudinally in the cap-stopper and a piston to operate in the dispensing-cylinder, each plunger being provided with a stop-rib, and with an opposite tooth or spur to cooperate with the rib in the bottle-neck, substantially as set forth.

18. A bottle-neck, provided with a bottom wall having a filling-port at one side and provided with an opposite discharge-port and with a tubular portion communicating with said discharge-port, and provided with an annular neck near its outer end with an annular groove having a stop-shoulder and beneath said groove with a longitudinally-extending rib, the cap-stopper having pawl devices operating in said groove, the cylinder having an opening cooperating with said filling and discharge ports, and the piston operating in said cylinder and having its shank passed through the cap-stopper, substantially as set forth.

697,879. FOLDING PARCEL-CARRIER. JOHN R. PHILLIPS, Stamford, Conn. Filed Feb. 22, 1902. Serial No. 95,702. (No model.)

Claim.—1. A folding parcel-carrier comprising two substantially trough-shaped members hinged together at their ends and adapted to fold together face to face, and a swinging hook on each member adapted to fold within the recess.

2. A folding parcel-carrier comprising two members formed to substantially trough shape and having corresponding hinge members at one end and slots at the other end and hooks pivoted to the hinge members contiguous to the slots and adapted to swing through the slots in the operative position and to fold within the members in the closed position.

2. A parcel-carrier consisting of two members having longitudinal recesses 20, corresponding hinge members at one end and slots at the other end, and hooks formed from a single piece of wire and pivoted in the recesses and adapted to fold within said recesses in the closed position and to pass through the slots in the operative position.

697,880. GATE. WILLIAM H. PLASTER, Cotton, Tex., assignor of one-half to Henry Plaster, Cotton, Tex. Filed Nov. 22, 1901. Serial No. 82,773. (No model.)

Claim.—1. The combination of a frame having a forwardly-tapering opening, guides arranged in pairs at the front and back of the opening, a swinging gate having an arm arranged in the opening of the frame, a pivoted plate mounted on the arm and the front and rear operating-rope arranged in pairs in the said guides and extending therefrom to the arm of the gate and connected with the plate, said operating-rope extending from the gate in opposite directions, substantially as described.

2. The combination of a horizontal frame having a forwardly-tapered opening, a swinging gate having an arm extending into the opening, pulleys or guides mounted on the frame in pairs at the front and back of the opening, the front operating-rope arranged in the front guides or pulleys and extended across the frame to opposite sides of the roadway, the rear operating-rope extending from the arm to the rear guides or pulleys and crossing the frame and extended to opposite sides of the roadway, a pivoted plate mounted on the arm and having the ropes secured to it and means for supporting the outer portions of the operating-rope, substantially as described.

697,881. FAUCET. JOHN C. FORT, Spokane, Wash., assignor to Forts Automatic Faucet Co., Incorporated. Filed Dec. 31, 1900. Serial No. 41,672. (No model.)

Claim.—1. The combination, substantially as described, of the main valve provided with a tubular portion and with a piston therein, a casing-section having a chamber in which the said piston operates and provided with a seat for the main valve and with ports opening into the faucet, a drainage-section abutting the upper end of the piston-chamber and provided with ports communicating with the faucet and also having a central guide for the starter-rod, the threaded cap for securing the valve mechanism in the said faucet and provided with an opening for the starter-rod and with a recess for the push-button or head thereof, the starter-rod having the push-button or head at its outer end and provided at its inner end with a valve, and above said valve with a chamber for conducting pressure to the piston-chamber and thence to the drainage-chamber and the head or disk on said starter-rod for operation by the supply-pressure, substantially as set forth.

2. The combination of the main valve, a seat and piston, a chamber in which the piston operates, a drainage-chamber, and means for admitting pressure to the piston-chamber for opening the main valve and for establishing communication between said chamber and the drainage-chamber when the main valve is closed, substantially as set forth.

3. A faucet provided with a valve mechanism comprising a main valve provided with a tubular portion and a piston held therein, a seat for said valve and a chamber in which its piston operates, a starting-rod operating in the tubular portion of the main valve and grooved forming a channel for the passage of water to the cylinder-chamber and a valve for shutting off the supply of water to said channel, and a disk or button connected with the starting-rod and arranged for operation by the supply-pressure, substantially as set forth.

4. The combination of the faucet-casing having a discharge-chamber and a drainage-chamber, and the valve mechanism fitted to the casing, and comprising a main valve provided with a piston, a chamber in which the piston operates, and starting mechanism by which to admit pressure to operate upon the piston for opening the main valve and for establishing communication between the piston-chamber and the drainage-chamber when the valve is closed, substantially as described.

5. A self-closing faucet provided with a valve and with means for operating the same and with a float having a channelled lower end and arranged in the supply-pipe in advance of said valve, and adapted to operate, substantially as shown and described.

6. In an automatic faucet, the combination of the main valve, the starting mechanism having a channelled stem or rod through which pressure may be applied to open the main valve, the outer end of the stem being arranged for manipulation by hand, substantially as described.

7. The combination, in a faucet, of the main valve and its piston, the drainage-section, the section having the chamber in which the valve-piston operates, and the stem extending through the main valve and channelled for the passage of pressure to the piston-chamber, said stem being removable longitudinally whereby its channel may open into the drainage-chamber when the main valve is closed, substantially as described.

8. The valve mechanism, substantially as described, comprising the cap-section, the drainage-section, the section provided with a chamber for the piston, the main valve having a tubular portion and a piston at the end thereof, and the starting mechanism having a longitudinally-removable stem provided with a channel, and the valve and the disk or button, all substantially as set forth.

9. A valve arranged to be opened and closed by the water-pressure and having a starting mechanism including a rod grooved spirally for the passage of the water substantially as set forth.

10. The combination of the faucet-casing having a main discharge-chamber and a drainage-chamber and a partition between the same having an opening for the valve mechanism and having in line with said opening a seat B for such mechanism, and the valve mechanism including the inner section fitting in said seat and in the opening in the partition, the section abutting said inner section and having ports opening into the drainage-chamber, the valve and starting device and means for securing the valve mechanism in the faucet-casing substantially as set forth.

11. The combination of the faucet-casing having an opening for the insertion of the valve mechanism and a seat for the inner end of the valve mechanism, the valve mechanism having a casing fitted at its inner end to the faucet-casing, devices threaded into connection with the faucet-casing and bearing against the outer end of the valve-casing and securing the latter firmly to its seat and the valve and starting device substantially as set forth.

12. A self-closing faucet consisting of a valve mechanism comprising a main valve a piston for opening the same, and a cylinder for said piston, a starting mechanism arranged to be operated by hand to admit pressure to said piston-chamber to operate the piston and means independent of said starting mechanism for limiting such pressure-operated movement of the piston substantially as set forth.

697,882. SAW-TOOTH CASE. ROBERT E. FURBER, Indianapolis, Ind. Filed Sept. 11, 1901. Serial No. 75,976. (No model.)

Claim.—1. In a saw-cut the combination, of the base formed with the saw, the die pivoted thereto to cooperate with said saw, the adjust-

able rest 3 with wings extending out therefrom at angles with a line extending straight across the saw, substantially as set forth.

2. In a saw-cut, the combination of the base having the saw thereon, a die pivoted thereto to cooperate with said saw, and a rest for the edge of the saw having wings extending back obliquely from the central point of rest, substantially as described and for the purpose specified.

3. A saw-cut comprising a base having an saw, a die pivoted to cooperate with said saw, and a rest for the edge of the saw extending back from said saw at an oblique angle, whereby the teeth is supported at the desired angle to the cutting-die, substantially as set forth.

4. In a saw-cut, the combination, of the base having an saw near one end, a die pivoted to cooperate therewith, a rest for the edge of the saw, and a rest for the side of the saw opposite the saw, and a pressure-finger mounted on the top of the base to extend forward over said rest for the side of the saw-blade to rear said saw, whereby said saw-blade is embraced between said rest and said pressure-finger except the extreme edge or teeth being operated upon, substantially as set forth.

5. In a saw-cut, the combination, of the base with the saw formed on its top, the die pivoted thereto to cooperate with said saw, the rest for the edge of the saw mounted to be adjusted longitudinally of said base and formed with lateral wings extending back at an oblique angle, and the pressure-finger, substantially as set forth.

697,888. SAW-TOOTH CASE. ROBERT E. FURBER, Indianapolis, Ind. Filed Oct. 2, 1901. Serial No. 77,964. (No model.)

Claim.—1. The combination, in a saw jointer and gage, of a gage-plate having a horizontal gaging-surface for the points of the teeth, and also a tapered gaging-surface for the sides of the teeth, substantially as set forth.

2. In a saw-jointer and gage, the combination, of the block and the gage-plate formed with a longitudinal slot through which the teeth project when being operated upon, and transverse grooves at each end of said slot formed with beveled sides to serve as a gage in forming the bevel of the teeth, substantially as set forth.

3. A gage-plate for forming the points of saw-teeth having a square top surface, and a transverse beveled surface, substantially as set forth.

4. A gage-plate for forming the points of saw-teeth having a separate form for both the points and sides thereof.

697,884. TROLLEY-POLE. WILLIAM FULLMAN and CHARLES G. FIELD, Boston, N. Y. Filed Oct. 11, 1901. Serial No. 78,368. (No model.)

Claim.—1. The combination of the trolley-pole, a pivoted carrier for said pole, a slidable locking-bolt for holding the trolley-pole in operative position, the lower portion of said bolt being adapted for contact with a fixed point to effect its movement to a releasing position, substantially as specified.

2. The combination of the trolley-pole, a pivoted carrier to which said pole is pivoted, the pivotal connection between the pole and its support being arranged in advance of the fulcrum-point of the carrier, and means for locking the pole to its support, substantially as specified.

3. The combination of the carrier, a pivoted support for said carrier, a trolley-pole pivotally connected to said support at a point in advance of the pivotal support of the carrier, means for locking the pole to the support, and a seat or support arranged at the rear of the fulcrum-point of the carrier and forming a fulcrum for the trolley-pole while the latter is being locked to its carrier, substantially as specified.

4. The combination of the carrier, a trolley-pole pivoted thereto, a spring connected to said carrier, a locking-belt with which said carrier is held in contact by said spring, the lower end of said belt being adapted for contact with a fixed point, and a seat or support forming a fulcrum for the trolley-pole while the latter is being locked to its carrier, substantially as specified.

5. The combination with a pivoted carrier or support, of a trolley-pole pivotally connected to said carrier or support at a point at one side of the pivot or fulcrum of said carrier, a locking member carried by the trolley-pole and adapted for engagement with said carrier at a point on the opposite side of said fulcrum, and a spring normally tending to hold said carrier in contact with said locking member, substantially as specified.

6. The combination with a pivoted carrier or support comprising a pair of carrying-plates of a trolley-pole pivoted between said plates, a slidable belt carried by said trolley-pole and having locking-dogs for engagement with said plates, a spring or springs connecting said plates to a fixed point, and a seat or support adapted to hold said trolley-arm when the latter is in inoperative position and forming a fulcrum-point for said trolley-pole when the latter is being locked to its carrier, substantially as specified.

697,885. CHEESE-BOX TRIMMER. HENRY W. QUARR, Water town, Wis. Filed Aug. 12, 1901. Serial No. 71,094. (No model.)

Claim.—1. A cheese-box trimmer, comprising a hand-operated frame having an overhanging bearing-plate adapted to rest and travel on a cheese, a cutter secured on the frame, and rollers journaled in the ends of the frame, one of the rollers being adapted to engage the outer face of the cheese-box rim, and the other roller being adapted to engage the inner face thereof, as set forth.

2. A cheese-box trimmer, comprising a hand-operated frame having an overhanging bearing-plate adapted to rest on a cheese, rollers for engaging the cheese-box rim at opposite faces, a block vertically adjustable in said frame, and a cutter extending transversely and secured to said block, as set forth.

3. A cheese-box trimmer, comprising a hand-operated frame having an overhanging bearing-plate adapted to rest on a cheese, rollers for engaging the cheese-box rim at opposite faces, a block vertically adjustable in said frame, and a cutter held transversely adjustable on said block, as set forth.

4. A cheese-box trimmer, comprising a frame, a bearing-plate secured thereon and adapted to rest on a cheese, a cutter carried by the frame, a roller for engaging the roller journaled on one end of the frame, and arranged to engage the outside of the cheese-box rim, a second roller for engaging the inner face of the cheese-box rim, and means adjustable on said frame and in which said second roller is journaled, as set forth.

697,886. GLASS-GATHERING MACHINE. DANIEL C. REPLY, Pittsburg, Pa. Filed Mar. 14, 1901. Serial No. 51,108. (No model.)

Claim.—1. In a glass-gathering device, a supporting-frame, said frame being movable toward and from the furnace, an axially-rotatable gathering-iron pivotally mounted in the frame, power-driven means for rotating the gathering-iron, and a handle or pilot by which said iron may be manually moved lengthwise within the furnace and tipped to and from the glass, substantially as described.

2. In a glass-gathering device, a supporting-frame, said frame being movable toward and from the furnace, axially-rotatable gathering-irons pivotally mounted in the frame, power-driven means for rotating the gathering-irons simultaneously, and a handle or pilot by which said irons can be manually moved lengthwise within the furnace and tipped to and from the glass, substantially as described.

3. A swinging frame, a shaft carried thereby and provided with worms, gathering-irons driven by the worms and carried by the frame, and an overhead driving-gear by which the shaft is rotated, substantially as described.

697,886.

697,887. METAL-WORKING MACHINE. WILLIAM H. ROSSMAN, Evansville, Ind. Filed May 6, 1901. Serial No. 58,004. (No model.)

Claim.—1. In a machine of the class specified, a pair of frames one of which is relatively fixed and the other of which is slidable upon said relatively fixed frame, and the slidable frame being movable backward to a position directly under the fixed frame, and having a plurality of holes extending lengthwise thereof and a loosely-mounted lever having a projection for entering one of said holes.

2. In a machine of the class specified, a pair of frames one of which is relatively fixed and the other of which is slidable upon said relatively fixed frame, and the slidable frame being movable backward to a position directly under the fixed frame, and having a plurality of holes extending lengthwise thereof, a loosely-mounted lever having a projection for entering one of said holes, a tool-carrying shaft upon the fixed frame, and a work-holder upon the movable frame.

3. In a machine of the class specified, a pair of substantially rectangular frames one slidably supported by and between the side bars of the other and having a perforated bar extending lengthwise thereof, a work-holder carried by one of the frames, a tool-carrying shaft on the other frame, and a lever the free end of which is adapted to enter one of the perforations of said perforated bar.

4. In a machine of the class described, a pair of parallel bars, bearings connected to said bars, a shaft supported by the bearings, a slide having side bars grooved to receive said parallel bars and also including a bar having a series of holes and a loosely-mounted lever having a pin to enter one of said holes.

5. In a machine of the class described, a pair of parallel bars, bearings connected to said bars, a slide consisting of a rectangular frame, the side bars of which have grooves to receive said parallel bars, and said slide including an intermediate bar in parallelism with the side bars, having a plurality of aligned holes, a lever having a longitudinal slot, and provided with a pin adapted to enter one of said holes, and a pin passing through said longitudinal slot.

6. In a machine of the class specified, a pair of frames one of which is relatively fixed and the other of which is slidable upon said relatively fixed frame, and the slidable frame being movable backward to a position directly under the fixed frame, and having a plurality of holes extending lengthwise thereof, a loosely-mounted lever having a projection for entering one of said holes, a tool-carrying shaft on one of the frames and a work-holder on the other frame, including a pair of jaws and each jaw having a pair of transversely-disposed intersecting jaws.

697,888. REFRIGERATOR. HENRIK ROSSMAN, Charlottenburg, Germany. Filed Jan. 2, 1902. Serial No. 65,971. (No model.)

Claim.—1. A refrigerator provided with a double-walled case having a suitable door-opening, a wooden frame secured to each wall around said opening, a non-conducting layer connecting the wooden frames of the inner and outer walls and surrounding the door-opening, a double-walled door adapted to close the door-opening, a wooden frame surrounding each wall of the door, and a non-conducting layer connecting and secured to said wooden frames of the door-walls and surrounding the space between said door-walls, substantially as described.

2. A refrigerator provided with a double-walled case having a suitable door-opening, a wooden frame secured to each wall around said opening, a non-conducting layer connecting the wooden frames of the inner and outer walls and surrounding the door-opening, and a non-conducting stay for the walls, comprising opposite wooden strips secured to the inner and outer walls, strips of asbestos board connecting said strips, and non-conducting packing in the space between the wood and asbestos strips, substantially as described.

697,889. TEMPORARY BLINDER. GEORGE A. BROWN, Vancouver, Canada. Filed Nov. 25, 1904. Serial No. 88,000. (No model.)

Claim.—1. A temporary blinder, comprising a casing, clamping devices detachably secured to the ends of the casing, adapted to extend over the edges of a cover, locking-bars hinged at one end to the casing to swing lengthwise thereof, and means for locking the free ends of the bars to the casing, as set forth.

2. A temporary blinder, comprising in combination; with a look-cover, a casing extended longitudinally thereof, locking-bars pivotally mounted on the one end of the casing to swing upward in a vertical plane, a look device in the other end of the casing for securing the free ends of the locking-bars to their closed position, clamp members detachably connected to the ends of the casing, adapted to clamp over the outer edges of the cover, whereby to hold the casing firmly on the cover, as specified.

3. A temporary blinder, comprising in combination, with a look-cover, a U-shaped casing extended longitudinally on the suitable part of the cover, locking-bars pivotally mounted on one end of the casing to swing upward in a vertical plane, a look device in the other end of the casing for securing the free ends of the locking-bars to their closed position, said casing having clamps for engaging the outer edges of the cover, and a leaf-spring secured to the bottom of the casing, extended lengthwise thereof, and having its free ends held to press upward in the direction of the locking-bars, all being arranged substantially as shown and described.

4. A temporary blinder, comprising a casing consisting of the three independent sections 1, 2, 3, adapted, when fitted together, to form a U-shaped body, the lower section 1 having a vertical end, and a hinge-plate journaled transversely of the casing on said end, a look device on the other end of the casing, and locking-bars pivotally secured at one end on the abutment hinge-plate, their other end being made to engage the look device when closed down, and means for detachably securing the casing to a look-cover, all being arranged substantially as shown and for the purposes described.

697,890. RAIL-ROAD. RICHARD C. BROWN, Chicago, Ill. Filed July 21, 1902. Serial No. 34,864. (No model.)

Claim.—In a rail-road a headless cleave of hard metal tapered from end to end with its smaller end of smaller diameter and its larger end of

greater diameter than the bore into which the cleave is to be driven, having a cylindrical bore of slightly greater diameter than that of the conducting-wire, and slotted from end to end, all substantially as and for the purposes specified.

697,891. AMUSEMENT APPARATUS. EMERY F. BURMAN, Brooklyn, N. Y. Filed Dec. 7, 1904. Serial No. 84,000. (No model.)

Claim.—1. An amusement device, comprising means constituting a disk or canal, a tower located adjacent to said means and having openings at its top and bottom, stairs running up into the tower, a shaft extending vertically through the tower, an exhaust-fan carried on the shaft at the upper part of the tower, a horizontal shaft mounted at the base of the tower and geared with the vertical shaft, means for driving the shaft, and a paddle-wheel carried on the horizontal shaft and working in said disk or canal.

2. An amusement device, comprising means constituting a disk or canal, a tower located adjacent to said means and having an opening at its bottom and an opening at its upper portion, stairs leading up the tower to the opening in the upper portion thereof, a shaft extending vertically through the tower, a fan carried on the upper part of the shaft, a horizontal shaft mounted at the base of the tower and geared with the vertical shaft, and means attached to the horizontal shaft, each means engaging with the means forming the disk or canal.

3. An amusement device, comprising a tower with an inner balcony in the upper portion thereof, an outer balcony opposite the inner balcony, the tower having an opening leading from one balcony to the other, a stair running through the tower and leading to the inner balcony, means forming a disk or canal adjacent to the tower, a horizontal shaft mounted in the base of the tower and projecting therefrom, means attached to the horizontal shaft and engaging with the means forming the disk or canal, a vertical shaft extending through the tower and geared with the horizontal shaft, and a fan at the upper end of the vertical shaft.

4. An amusement device, comprising means constituting a disk or canal, a tower located adjacent to said means and having openings at its top and bottom portions, stairs running up into the tower, a shaft extending vertically through the tower, a fan carried on the shaft at the upper part of the tower, a cowl mounted locally on the shaft above the tower, a wind-wheel and vane carried in the cowl, and means geared with the vertical shaft and engaging with the said means forming the disk or canal.

697,892. TROLLEY-WHEEL. WILLIAM SULLMAN, Everett, Mass. Filed Jan. 21, 1902. Serial No. 33,000. (No model.)

Claim.—1. A trolley-wheel having two hubs, an annular partition which is arranged between the outer ends thereof, two cylindrical bearings which are oppositely arranged in said hubs so that their ends engage opposite sides of said partition, an aligning-shaft which is arranged in both bearings, and means for connecting the outer ends of said bearings to the support of the wheel.

2. A trolley-wheel having two hubs, an annular partition which is arranged between the outer ends thereof, two relatively short bearings which are oppositely arranged in said hubs so that their ends engage opposite sides of said partition, means for holding said bearings in alignment, and means for connecting the outer ends of said bearings to the support of the wheel.

3. A trolley-wheel having two hubs, an annular partition which is arranged between the outer ends thereof, two bearings which are oppositely arranged in said hubs so that their ends engage opposite sides of said partition, flanges on said bearings which are adapted to engage the outer ends of said hub, an aligning-shaft which is arranged in both bearings, and means for connecting the outer ends of said bearings to the support for the wheel.

4. A trolley-wheel having two hubs, two bearings which are oppositely arranged therein, means for securing the outer ends of said bearings to a support for the wheel, said bearings being axially bored from their inner ends partly through to their outer ends, forming closed recesses therein, and an aligning-shaft which has its ends arranged and fitted in said recesses, said wheel being provided with an oil-passage which leads to the recess about said shaft between the ends of said bearings.

697,898. DAMPER FOR FIREPLACES. SAMUEL SHAW, Boston Mass. Filed May 2, 1901. Serial No. 58,613. (No model.)

Claim.—In a damper, the combination with a casing having a flange, of a damper pivoted in said casing and having a shaft projecting therefrom above the flange, an arm on said shaft, a head secured to said flange and extending over the damper-shaft and arm, an operating-shaft journaled in said head, and a worm on said operating-shaft within the head and in engagement with said arm, said operating-shaft having a suitable handle at its outer end.

697,894. WEIGHING-TONGUE. WILLIAM F. SMILEY, Philadelphia, Pa. assignor of one-half to Charles A. Hestett, Philadelphia, Pa. Filed Nov. 4, 1901. Serial No. 58,978. (No model.)

Claim.—1. A weighing-scale, a handle connected with the casing thereof, a vertically-arranged sliding bar mounted on said casing, a han-

dle on the upper end of the said bar, lazy-tongs levers depending from a weighing member of said scale and having their upper axis connected with the same, and grappling-tongs connected with the lower axis of said levers, said bar being connected with said levers by said lower axis, the parts named being combined forming an improvement in weighing-tongs.

2. Lazy-tongs levers, grappling-tongs connected with the lower members thereof, a weighing-scale, a handle thereon, a movable member of said scale being connected with the upper axis of said levers, a sliding bar mounted on said casing, the lower axis of said levers being connected with the lower end of said bar and a handle on the upper end of said bar adjacent to the handle of the scale.

3. A weighing-scale, lazy-tongs levers, a link connecting the upper axis of said levers with a movable weighing member of said scale, grappling-tongs continuous of the lower pair of said levers, and a vertically-movable bar mounted on the scale and connected with the lower axis of said levers, said link being deflected partly from its broad side presenting the same to the front where it is connected with said upper axis of the levers.

697,895. COPY-HOLDER AND LINE-INDICATOR FOR TYPE-WRITING MACHINES. FRANK C. SMOOTH, Allegheny, Pa. Filed Apr. 11, 1901. Serial No. 58,301. (No model.)

Claim.—A copy-holder comprising a frame and support therefor, said frame having an elongated slot, a shaft carried by said support, a pinion-wheel keyed to said shaft, a rack-bar on each longitudinal edge of said frame, an indicator 20 having its ends angled and secured respectively to said rack-bars, a lug on each end of said indicator projecting beyond the rack-bar, and engaging said elongated slot in the frame, a ratchet-wheel mounted on said shaft, an escapement and a lever connected therewith for allowing said ratchet-wheel to make an intermittent rotary movement under the influence of the weight of the rack-bars, as shown and described.

697,896. ANCHOR-BUSHING FOR SCREWS. DR. WILLIAM S. SMITH, Springfield, Mass. Filed Nov. 31, 1901. Serial No. 58,112. (No model.)

Claim.—1. An anchor-bushing for screws consisting of a cylinder of metal adapted to receive the threads of a screw, said bushing having a cylindrical hole therethrough of less diameter than a screw for entering it, there being saw-cuts extending diametrically through said bushing from said hole and toward the opposite end, and located in planes at an angle one to the other.

2. An anchor-bushing for screws consisting of a cylinder of metal adapted to receive the threads of a screw, said bushing having a cylindrical hole therethrough of less diameter than a screw for entering it, there being saw-cuts extending diametrically through said bushing from each end toward the opposite end, and each extending past the other in places at an angle to each other.

697,897. CULTIVATOR-SHOVEL. THOMAS E. SMITH, Menasha, Ill., assignor of one-half to Elmer E. Randolph, Menasha, Ill. Filed Aug. 1, 1901. Serial No. 70,446. (No model.)

Claim.—1. A cultivator-shovel comprising an upper and a lower section, a support for the said sections, the same being attached to the upper one and which consists of the hollow housing C for attachment to the cultivator, the diverging arm D D extending downward below the lower extremity of the upper section and to which the lower section is attached by bolts as shown, the adjacent edges of said sections being beveled substantially as and for the purposes set forth.

2. A cultivator-shovel comprising an upper and a lower section A and B respectively, the same abutting at their edges and beveled as shown, the one-piece support consisting of the hollow housing C for attachment to the cultivator and also having the upper section A secured thereto, the downwardly and outwardly extending arms D D of said support projecting below the abutting edges of the sections and having the lower section B secured thereto by bolts, the said lower section being detachable from said support substantially as described and for the purposes set forth.

697,898. PROCESS OF PURIFYING ZINC-BEARING SOLUTIONS. CARL E. F. BRUNNEN, Cleveland, Ohio. Filed Jan. 12, 1901. Serial No. 42,891. (No specimen.)

Claim.—1. The process of purifying zinc-bearing solutions containing copper, lead, arsenic, cadmium and other metals kindred with zinc, which consists in treating such solutions with zinc powder, that is to say, with a mixture of about seventy-five parts of zinc and about twenty parts of zinc acid, to precipitate the copper, lead, arsenic, and cadmium and to simultaneously reduce the amount of any free acid the solution may contain.

2. The process of purifying zinc-bearing solutions containing copper, lead, arsenic, cadmium, or metals kindred with zinc, which consists in treating the solutions with unacidified iron and zinc powder consisting of zinc proper and zinc acid in the proportions of about seventy-five to twenty parts, respectively, as described.

3. The process of purifying zinc-bearing solutions, containing iron, manganese, cobalt, which consists in treating such solutions with zinc powder, to precipitate the metals kindred with zinc, then removing any iron and manganese that may be contained in the solution, and, lastly, again treating the partly-purified solution with zinc powder, to precipitate the cobalt and nickel, as described.

4. The process of purifying zinc-bearing solutions containing hydrochloric acid, iron, manganese, cobalt, nickel, copper, lead, arsenic, cadmium or other metals kindred with zinc, which consists in treating the solutions with zinc powder, to precipitate those metals which are kindred with zinc, then removing any iron and manganese that may be contained in the solution, then treating the latter with the hydrate of an alkali and with the hydrochloric of the same alkali, to remove part of the cobalt and nickel, and, lastly, again treating the partly-purified solution with zinc powder, to precipitate the remainder of cobalt and nickel as described.

697,899. GOVERNOR FOR MARINE ENGINES. BRADFORD W. SISK, Mount Holly, N. J., assignor, by mesne assignments, to the International Marine Governor Company, a Corporation of New Jersey. Filed May 17, 1901. Serial No. 68,668. (No model.)

Claim.—1. A governor for a marine engine for preventing or reducing

ing racing, consisting of a chamber, a fluid therein, a plunger occupying said chamber and adapted to be controlled by the level of said fluid, a beam controlled by the motion of said plunger, and a connection between said beam and the supply-valve of said engine, consisting of a rocker, a link attached to a member of said beam and rocker and an arm connected with said rocker and the lever of said valve.

2. A governor for a marine engine for preventing or reducing racing, consisting of a chamber, a fluid therein, a plunger occupying said chamber and adapted to be controlled by the level of said fluid, a beam controlled by the motion of said plunger, and a connection between said beam and a supply-valve of said engine, said connection consisting of a rocker, a link attached to a member of said beam and rocker, and an arm connected with said rocker and the lever of said valve, said member, rocker and arm being provided with means for adjustment of the same.

3. A governor for a marine engine for preventing or reducing racing, consisting of a chamber, a fluid therein, a plunger occupying said chamber and adapted to be controlled by the level of said fluid, a beam controlled by the motion of said plunger, a connection between said beam and the supply-valve of said engine, consisting of a rocker, a link attached to a member of said beam and rocker and an arm connected with said rocker and the lever of said valve, and means for disconnecting said lever from said arm.

4. A governor for a marine engine for preventing or reducing racing, consisting of a chamber, a fluid therein, a plunger occupying said chamber and adapted to be controlled by the level of said fluid, a beam controlled by the motion of said plunger, and a connection between said beam and the supply-valve of said engine, consisting of a rocker, a link attached to a member of said beam and rocker and an arm connected with said rocker and the lever of said valve, and means for disconnecting said lever and arm, said member, rocker and arm being provided with means for adjustment of the same.

697,900. SEED-SOWING MACHINE. DEBORAH SUMNER, Pleasant Township, Wapello county, Iowa. Filed Jan. 17, 1902. Serial No. 80,131. (No model.)

Claim.—1. In a seed-sowing apparatus, the combination of a support, a hopper mounted thereon and having two separate seed-discharge openings in its bottom, devices below each seed-opening for metering the seed, two out-off plates attached to the hopper-bottom and extending or diverging from said seed-openings to a point at one side of the hopper, the outer ends of these plates being overlapped and pivotally connected together, means on the hopper for guiding these plates to and from the respective seed-openings as said plates are moved in and out to adjust the openings, and a single operating device connected to the overlapped ends of the plates, for the purposes set forth.

2. In a seed-sowing apparatus, the combination of a support, a hopper mounted thereon and having two separate seed-discharge openings in its bottom and also two curved guides diverging respectively from said seed-openings to a point at one side of the hopper, means supported below the hopper-bottom for centering the seed, two curved out-off plates mounted respectively in said guides and extending from the seed-openings to a point at one side of the hopper where they are connected together, a single operating-lever connected to the connected ends of the guides for simultaneously sliding said plates to and from the seed-openings.

697,901. LAMP-BRACKET. ALFRED THURMER, Veroville, Cal.
Filed June 14, 1901. Serial No. 64,744. (No model.)

Claim.—1. A lamp-bracket having at its outer end a horizontal plate provided with a raised portion, in combination with lamp-holding jaws provided with rearwardly-extending arms, the inner ends of which are mounted upon said plate, and a casing having one end open and the lower edges of its sides and closed end provided with retaining-flanges adapted to be slid over the ends of said arms and horizontal plate.

2. A lamp-bracket having at its outer end a horizontal plate provided with a raised portion, said raised portion being wider at its inner end than at its outer end, in combination with lamp-holding jaws having rearwardly-extending arms, the inner ends of which terminate in a loop and fit about the raised portion of said plate, and a housing or casing adapted to be slid over said horizontal plate.

3. In a lamp-bracket, the hinged swinging arm having the horizontal plate and the raised portion on its upper surface which gradually decreases in width from its inner end, in combination with a pair of semi-circular lamp-holding jaws having their inner ends bent to form a loop and fitting about said raised portion, a clamp mounted upon one of said arms, and an enclosing casing fitting over the inner ends of said arms and the bracket-plate.

697,902. LINCOLN-CUTTER. FREDMAN L. TRIPP, Hlansburg, Wash. Filed Jan. 21, 1902. Serial No. 66,042. (No model.)

Claim.—1. A Lincoln-cutter, comprising a pair of longitudinal bars of the same width, means for tentatively securing said longitudinal bars in registry with each other upon opposite sides of the substance to be cut, and a hand-operated member of substantially the same width as one of said bars, for traveling along the surface of the same, said member being provided with a depending knife and a depending guide-plate straddling said bar and engaging the edges thereof.

2. A Lincoln-cutter, comprising a pair of longitudinal bars of the same width, means for tentatively securing said bars in registry with each other upon opposite sides of the substance to be cut, and a convex member for engaging one of said bars, said convex member being provided with a knife and guide-plate for engaging opposite edges of said last-mentioned bar, and also provided with a handle, the arrangement being such that said convex member is free to rock upon the said bar which it engages.

3. A Lincoln-cutter, comprising a pair of flat bars of uniform width for engaging opposite sides of the Lincoln to be cut, one of said bars being provided with a clamp and the other being beveled to engage said clamp, and a cutter consisting of a manually-operated rocker-like member of the same width as one of said bars, and provided with a guide-plate

and a knife secured respectively upon its opposite sides, the arrangement being such that said member is free to travel along one of said longitudinal members, said guide-plate and said knife serving to keep the same accurately in register with the edges of said bars.

697,903. FLOUR-SIFTER. WILLIAM M. VINEY, Harrodsburg, Ky. Filed July 26, 1901. Serial No. 66,227. (No model.)

Claim.—1. A sifter comprising of an open-ended body, a sieve therein, an external rotatable handle, an agitator cooperating with the sieve and having a stem projected outwardly through the body and fulcrumed therein, and an operative connection between the rotatable handle and the agitator.

2. A sifter comprising a body, a sieve therein, a rotatable handle, an agitator cooperating with the sieve and provided with a stem projected outwardly through the body and fulcrumed therein, and a crank-arm carried by the rotatable handle and loosely connected to the outer end of the stem.

3. A sifter comprising a body, a sieve therein, opposite handle-brackets projected outwardly from the body, a rotatable handle mounted between the brackets, an agitator cooperating with the sieve and provided with a stem projected outwardly through an opening in the body and located below the lower handle-bracket, the stem forming a closure for the opening and also having an intermediate fulcrum connection with the edges of said opening, and a crank-arm carried by the lower end of the rotatable handle and having a pivotal connection with the outer end of the stem, said pivotal connection being located between the handle and the body of the sifter.

697,904. RAILWAY. ALONZO WHEA, Sumner, Ky. Filed Oct. 2, 1901. Serial No. 77,208. (No model.)

Claim.—1. The combination with railway-rails, of ties, a trans carried by said ties and means carried by said rails to hold the ties from spreading to prevent displacement of said trans.

2. The combination with railway-rails, of ties having recesses, a trans resting in said recesses, and angle-irons for preventing the spreading of said ties.

3. The combination of ties having inclined recesses, a beveled trans adapted to fit in said recesses, and angle-irons secured to the bases of the rails for preventing spreading of the ties.

697,905. SUSPENDER. ELIAS WHITMAN, Brooklyn, N.Y. Filed Dec. 14, 1901. Serial No. 66,222. (No model.)

Claim.—1. A convertible support for trousers, comprising two straps having overlapped ends, means for connecting said ends whereby the straps may be disposed to form a belt or arranged to pass over the shoulders of a wearer, links on the free ends of said straps, and clip-plates attached to said links, each plate having a slot reduced in width at one end and a button on each plate located a distance from the reduced end of the slot, substantially as specified.

2. A convertible support for trousers, comprising two straps having overlapping ends, ring-plates between which the straps pass, a pivot passing through said ring-plates and through the straps, an offset on one of the plates, a tongue in the offset, a button on the tongue and fastening-clip at the free ends of the straps, substantially as specified.

3. A convertible support for trousers, comprising straps having overlapped ends, a ring-plate engaging against the inner side of one of said straps and having a cross-bar, a ring-plate engaging against the outer

side of the other of said straps and having a cross-bar, a pivot passed through the said cross-bar and through the straps, a button carried by one of said ring-plates, a suspender-end adapted for removable engagement with said button, clips on the free ends of the straps, and suspender-ends having removable connection with said clips, substantially as specified.

697,906. TORPEDO-LAUNCHING APPARATUS. JOHN WHITEHEAD, France, Austria-Hungary. Filed July 24, 1901. Serial No. 69,594. (No model.)

Claim.—1. In an apparatus for firing off torpedoes under water from the broadside of moving vessels in combination with a torpedo-tube casing and a torpedo-tube adapted to move therein a piston at the rear or inner end of the torpedo-tube tightly fitting the inner cylindrical end of the torpedo-tube casing and a torpedo guide-shield composed of folding doors secured to the front end of the torpedo-tube, a valve for admitting fluid under pressure into the casing in rear of the torpedo-tube, and means for increasing the width of the passage uncovered by the said valve progressively as the torpedo-tube moves outward in the casing, substantially as described.

2. In an apparatus for firing off torpedoes under water from the broadside of moving vessels in combination with a torpedo-tube casing, a torpedo-tube having a piston at its rear and tightly fitting the inner cylindrical end of the torpedo-tube casing and a guiding-shield at its front end, a valve for admitting fluid under pressure into the casing in rear of the torpedo-tube, a screw connected with said valve, a rack on the torpedo-tube, a pinion journaled on the torpedo-tube casing and engaging with said rack, and gearing intermediate between the said pinion and the screw, substantially as and for the purpose set forth.

3. In an apparatus for firing off torpedoes under water from the broadside of moving vessels in combination with a torpedo-tube casing, a torpedo-tube having a piston at its rear and tightly fitting the inner cylindrical end of the torpedo-tube casing, a series of the upper doors hinged on bars secured to the front end of the torpedo-tube and parallel to the axis of said tube a series of lower doors hinged on and adapted to move

along bars secured to the front end of the torpedo-tube, locking-lugs secured to the upper edge of the lower doors and adapted to enter lengthwise into holes in the lower edge of the upper doors, and means for turning both sets of doors on their hinge-bars and for moving the lower doors along their hinge-bars substantially as and for the purpose described.

4. In an apparatus for firing off torpedoes under water from the broadside of moving vessels in combination with a torpedo-tube casing having an enlarged rectangular outer end and a cylindrical inner portion, a torpedo-tube having a piston at its rear and tightly fitting the inner cylindrical end of the torpedo-tube casing a series of the upper doors hinged on bars secured to the front end of the torpedo-tube and parallel to the axis of said tube, a series of the lower doors hinged on and adapted to move along bars secured to the front end of the torpedo-tube locking-lugs secured to the upper edge of the lower doors and adapted to enter lengthwise into holes in the lower edge of the upper doors, means for turning both sets of doors on their hinge-bars, means for moving the lower doors outward along the hinge-bars an arm adapted to turn on the hinge-bar of each of the lower doors, a link connecting each arm with the lower door, and a guide-roll in the enlarged front end of the torpedo-tube casing for the said arm to slide upon substantially as and for the purpose described.

5. In an apparatus for firing off torpedoes under water from the broadside of moving vessels in combination with a torpedo-tube casing having an enlarged rectangular outer end and a cylindrical inner portion, a torpedo-tube having a piston at its rear and tightly fitting the inner cylindrical end of the torpedo-tube casing a series of upper doors hinged on bars secured to the front end of the torpedo-tube and parallel to the axis of said tube, a series of lower doors hinged on and adapted to move along bars secured to the front end of the torpedo-tube, locking-lugs secured to the upper edge of the lower doors and adapted to enter lengthwise into holes in the lower edge of the upper doors, means for turning both sets of doors on their hinge-bars, a lever pivoted to the torpedo-tube adapted to be engaged by a projection on the torpedo-tail when the latter leaves the torpedo-tube, a rod guided on the torpedo-tube and adapted to push upward the lower doors along their hinge-bar, link-and-lever gearing carried by the torpedo-tube casing with pneumatic-power-furnishing devices and link-and-lever gearing with the pneumatic device being adapted to transmit motion from the said lever to the said rod and means for moving the lower doors, inward along the hinge-bars, substantially as and for the purpose described.

6. In an apparatus for firing torpedoes under water from the broadside of ships a guiding-shield comprising a set of upper doors hinged at the top to a bar parallel to the axis of the torpedo-tube, a set of corresponding lower doors hinged at the lower edge on and movable along a bar parallel to the axis of the torpedo-tube, projections on the upper edge of the lower doors carrying locking-lugs adapted to enter lengthwise into holes in projections on the lower edge of the upper doors and a spring-actuated lock-lever pivoted to either of the doors and adapted to enter between the projections of the upper and lower doors and to be forced out from between such projections by the torpedo on its entering the guiding-shield substantially as and for the purpose described.

697,907. OFFICE-INDICATOR. WILLIAM W. WILDER, JR., Cincinnati, Ohio. Filed July 20, 1901. Serial No. 70,000. (No model.)

Claim.—1. In an office-indicator the combination of a base-plate, a forwardly-projecting post thereon, a face-plate having slots therein secured to the base-plate, concentric sign-bearing disks mounted between the base and face plate and being perforated to pass the post, a key to pass over said post and means for holding it at points upon the post opposite to the respective disks to engage them to expose various data at the slots in the face-plate, substantially as shown and described.

2. In an office-indicator the combination of a base-plate, a face-plate having slots cut therein, a series of circular concentric disks mounted rotatably between said plates the disks decreasing in diameter from the base-plate outward with the exception of the outermost which has a segment

out out to expose the other disks said outermost disk bearing signs upon its face and the others upon their edges, and means for rotating the disks to expose the signs at the slots of the face-plate, substantially as shown and described.

3. In an office-indicator the combination of a base-plate, radial arms secured thereto about a common center each having a similar series of parallel inwardly-projecting flanges at increasing distances from the base-plate and decreasing distances from the center forming circular ways, sign-bearing disks seated in the ways formed by the similar flanges, a slotted face-plate and means for rotating the disks to expose the signs at the slots, substantially as shown and described.

4. In an office-indicator the combination of a slotted face-plate, a base-plate, a stud bearing a series of annular heads secured to the base-plate, a series of disks between the base and face plate having notched perforations to pass the post and slanted at distances apart equal to the distances apart of the annular heads, and a key having a hollow shank to fit over the post a spring-finger to engage the post between the heads and teeth to engage the notches in the disks to rotate them to expose different signs at the slots, substantially as shown and described.

697,908. CARD OR SIGN HOLDER. FRANK F. WELSH, Salt Lake City, Utah. Filed July 6, 1901. Serial No. 67,371. (No model.)

Claim.—1. A card or sign holder comprising two members having oppositely-projecting clamping-jaws at their outer ends and hinged together at the inner ends of their body or fixed members; substantially as described.

2. A card or sign holder, comprising two longitudinally-aligned clamps, two corresponding members of which are hinged together adjacently at their adjacent ends; substantially as described.

3. A card or sign holder, comprising two longitudinally-aligned clamps, ears, and a knuckle on the adjacent ends of corresponding members of said clamps, and a set-screw passing through the said ears and knuckles; substantially as described.

4. A card or sign holder, comprising two longitudinally-aligned clamps pivoted together at the adjacent ends of corresponding members, one of said members being provided with a foot to steady it when serving as a base for the other clamp; substantially as described.

5. A card or sign holder, comprising two longitudinally-aligned clamps pivoted together at the adjacent ends of two corresponding members, one of said members having transverse apertures, and a U-shaped foot, the legs of which are passed through said apertures; substantially as described.

6. A card or sign holder comprising two clamping members or jaws to receive the card or sign between them, and a sliding suspension-hook mounted on the outer side of one of said members or jaws; substantially as described.

7. A card or sign holder, comprising the duplex clamp, a guide or sheath on one member having a set-screw, and a hook, the shank of which is mounted in said guide or sheath; substantially as described.

8. A card or sign holder, comprising two longitudinally-aligned oppositely-projecting clamps, hinged together at the inner ends of corresponding members, a transverse sliding foot, and a suspension-hook; substantially as described.

697,909. APPARATUS FOR COATING METAL PLATES. JOHN E. WILLIAMS, Abertillery, England. Filed June 10, 1901. Serial No. 68,908. (No model.)

Claim.—1. Apparatus for coating tin, terne and like plates, comprising a coating-bath, oppositely-movable plate-carriers mounted therein and means whereby said plate-carriers may be caused to travel forward and backward alternately from the receiving end to the delivery end of the bath, and from the delivery end to the receiving end, and to pass each other in transit substantially as described.

2. Apparatus for coating tin terne and like plates comprising a coating-bath, oppositely-movable plate-carriers pivotedly mounted therein adapted to carry the plates edgewise and means whereby said plate-carriers may be caused to travel backward and forward alternately in the bath and to pass each other during this movement substantially as described.

3. Apparatus for coating tin terne and like plates comprising a coating-bath, oppositely-oscillating plate-carriers mounted therein and provided with means adapted to carry the plates edgewise, means whereby said plate-carriers may be caused to travel backward and forward alternately in the bath and to pass each other during this movement and means

for causing the simultaneous oscillation of said carriers substantially as described.

4. An apparatus for coating plates comprising a bath, a plate-carrier pivotedly supported at its upper end and depending into said bath and provided at its lower end with means for holding a plate edgewise, and means for oscillating said plate-carrier edgewise, for the purpose set forth.

5. Apparatus for coating tin, terne and like plates, comprising a coating-bath, oscillating plate-carriers pivotedly depending therein and adapted to describe a sector-like path, plate-clipping devices mounted on said carriers, means for oscillating said carriers, comprising a pinion attached to one of the pivots of each plate-carrier, a reciprocating rack-bar for each pinion, connecting-rods connected to said racks, and a crank-shaft connected to said racks, substantially as described.

697,910. FISHING-GEAR. ALBERT W. WILSON, San Francisco, Cal. Filed Dec. 13, 1901. Serial No. 68,909. (No model.)

Claim.—1. A fishing-gear, comprising a concave-convex spoon, a hook connected to the convex side thereof within the line of its longitudinal center, and means for connecting the fish-line to the front end of the spoon, said means being situated at one side of the longitudinal center of the spoon.

2. A fishing-gear, comprising an elongated spoon, a fish-hook connected thereto adjacent to its tail, and means for attaching a line to the spoon, said means being located at one side of the longitudinal center of the spoon.

3. A fishing-gear, comprising a concave-convex spoon, a hook having the end of its shank pivotedly connected to the convex side of the spoon adjacent to its tail, but removed from the marginal edge of the spoon, and means for connecting the fish-line to the front end of the spoon.

4. A fishing-gear, comprising a concave-convex spoon, a hook having the end of its shank pivotedly connected to the convex side of the spoon adjacent to its tail, but removed from the marginal edge of the spoon, and means for connecting the fish-line to the front end of the spoon, said means being situated at one side of the longitudinal center of the spoon.

5. A fishing-gear, comprising a concave-convex spoon, a hook connected thereto within the line of its longitudinal center, and means for connecting the fish-line to the front end of the spoon at one side of the longitudinal center of the spoon.

697,911. ADJUSTABLE COUNTER-STOOL. ASHURA ABLE, Tacoma, Wash. Filed Sept. 20, 1901. Serial No. 70,670. (No model.)

Claim.—1. In a stool, the combination with a bell-shaped base and bell-shaped top piece, of the intermediate telescoping sectional tubular standard, a cup or sleeve member to the bell-shaped portions in which the standard fits so as to be removable therefrom, and a ball and spring for holding the sleeve member and standard together, the standard and sleeve being formed one with an annular groove and the other with an aperture to receive the ball, substantially as described.

2. A stool comprising a base, a seat, an intermediate standard, and a cup or sleeve member with which the standard telescopes, one of said parts having a ball-socket and the other an aperture in its wall, a ball in said aperture, and a spring for pressing the ball into the ball-socket, substantially as described.

3. A stool comprising a base, a seat, an intermediate standard, and

a cup or sleeve member with which the standard telescopes, one of said parts having a ball-cocket and the other an aperture in its wall, a ball in said aperture, and a spring pressing the ball into the ball-cocket, said spring being formed with an opening in which a portion of the ball fits, substantially as described.

4. A steel comprising a base, a cast, an intermediate standard, and a cup or sleeve member with which the standard telescopes, one of said parts having a ball-cocket and the other an aperture in its wall, a ball in said aperture, a spring for pressing the ball into the ball-cocket, and a stop for limiting the movement of the standard and sleeve member one within the other, substantially as described.

687,912. APPARATUS FOR DISTILLING WATER. ANDREW J. CLARK, Boston, Mass. Filed June 26, 1901. Serial No. 66,081. (No model.)

Claim.—1. In a water-still having an evaporating-boiler and a condenser; in combination therewith, a centrally-located filter vertically placed between the evaporator and condenser and so arranged that all ascending vapor and air pass through the said filter; substantially as shown and described.

2. In a water-still having an evaporating-boiler and a condenser, in combination therewith, a filter concentrically located above the sterilizing-chamber, manifold air-holes permitting air to commingle with the vapor below the said filter, said filter so arranged that the air and vapor is forced to pass through it, in its ascent before it can reach the condensing-cham-

ber and the escape-vent of the still, and a water-reservoir surrounding said filter, arranged substantially as shown and described.

3. In a water-still having an evaporating-boiler and a condenser; in combination therewith a manifold of inlet air-holes into the sterilizing-chamber below the filter, a filter and a reservoir occupying the whole area within the still compelling the commingling of the vapor and air before passing through said filter to be condensed, a condensing-surface above said filter and a reservoir for receiving the condensed vapor; substantially as shown and described.

4. In a water-still having an evaporating-boiler and a condenser; in combination therewith a filter provided with filtering material located within the still proper and so arranged that through said filter all air and vapor in its ascent must pass previous to condensation; substantially as shown and described.

687,918. CLUTCH. WILLIAM E. GOSSETT, Portland, Oreg. Filed Nov. 12, 1901. Serial No. 22,121. (No model.)

Claim.—1. The combination with a shaft; bearings for said shaft; mechanism carried by said shaft between said bearings; and a clutch for locking said mechanism with said shaft; of means acting with the shaft outside of the bearings for throwing said clutch into and out of engagement with a yielding or frictional pressure, said means being arranged to confine the thrust for setting the said clutch to said shaft and the parts carried by said shaft.

2. The combination with a shaft; bearings for said shaft; mechanism carried by said shaft between said bearings; and a clutch for locking said mechanism with said shaft; of a system of gears carried by said shaft outside the bearings; and means acting with said gears for actuating said clutch through the action of the shaft, said means being arranged to confine the thrust for setting said clutch to the shaft and the parts carried by said shaft.

3. The combination with a shaft; bearings for said shaft; mechanism carried by said shaft between said bearings; and a clutch for locking said mechanism with said shaft; of a system of gears carried by the shaft outside the bearings; and means acting with said gears for throwing said clutch into and out of engagement, said means being arranged to confine the thrust for setting said clutch to said shaft and the parts carried by said shaft.

4. The combination with a shaft; bearings for said shaft; mechanism carried by said shaft between said bearings; and a clutch for locking said mechanism with said shaft; and a system of gears normally moving with the shaft; means carried by said shaft and arranged to act with said gears to actuate said clutch when a part is retarded, said means being also arranged to confine the thrust for setting said clutch to said shaft and the parts carried by said shaft; and means for retarding a part of said gear system.

5. The combination with a shaft; bearings for said shaft; mechanism carried by said shaft between said bearings; and a clutch for locking said mechanism with said shaft; of a system of gears normally moving with the shaft; means carried by said shaft and arranged to act with said gears to throw the clutch into engagement when one part is retarded and throw the clutch out of engagement when another part of said gear system is retarded, said means being also arranged to confine the thrust for setting said clutch to said shaft and the parts carried by said shaft; and means for retarding the different parts of said system to throw said clutch into and out of engagement.

6. The combination with the shaft A; clutch carried by said shaft; the bearings B & C for said shaft; the pin I for communicating a thrust movement from without the bearing B to the clutch; a shaft extension outside of the bearing B; two gears journaled on said shaft extension; an intermediate gear between said gears; a carrier for said intermediate gear fixed with the shaft extension; and means for retarding either of the gears journaled on the shaft extension; a screw arranged in the shaft extension

against the pin I; and means for communicating the action of the gear to the screw.

7. The combination with the shaft A; the clutch carried by said shaft between the bearings B B; the bearings C C; the pin I for communicating the thrust to the clutch through the bearing B; the shaft extension J; the screw H arranged in said shaft; the beveled gear K K' journaled on said shaft extension; the carrier L' fixed on said shaft extension; the intermediate gear L journaled on said carrier and meshing with the gear K K'; the rim A' extending from the gear K K' respectively; brake mechanism for said rim; and a spline-and-groove connection between the screw H and the gear K.

697,914. BRICK. FRANK CHAFFIN, Chicago, Ill. Filed May 20, 1901. Serial No. 61,697. (No model.)

Claim.—1. A brick having a plain outer face and an upper and lower portion plain for a short distance back of the corner of the outer face, and a weakened or breaking line at its middle portion.

2. A brick having a plain outer face, a groove midway of the length of the brick, and extending around the other three sides but stopping short of the corner made by the outer face and the top and bottom surfaces.

697,915. BOTTLE OR JAR PRESS. JEREMIAH HADLEY, ALTON, Ohio. Filed Feb. 10, 1901. Serial No. 61,700. (No model.)

Claim.—1. In a machine of the class designated the combination with a supporting-table having vertical parallel guides, and a blank-mold, of a cross-head to slide in said guides, having a vertical orifice, a screw-threaded hollow shaft in said orifice, adjustably secured therein, a cross-head below said first cross-head secured to the lower end of said hollow shaft, a rim-mold below said second cross-head sustained by rods supported and slidable in a plate adjustably secured between the first and second cross-heads, and pressed downward by springs resting against said plate, a third cross-head below said rim-mold with a neck-mold sustained therein sustained by rods slidable in the second cross-head, and adapted to fit said form an annular top for the blank-mold, a shaft within said hollow shaft spring pressed at the top and bearing a plunger to enter the neck and blank mold, and means for vertically reciprocating said upper cross-head, substantially as shown and described.

2. In a machine of the class designated the combination with a supporting table having vertical parallel guide-rods, a cross-head arranged to slide therein carrying a hollow shaft adjustably secured therein attached to a second lower cross-head, a vertically-sliding spring-pressed shaft within the hollow shaft bearing a plunger, and a spring-pressed rim-mold below the second cross-head sustained by rods passing through the two

and cross-heads slidable secured in a plate adjustably secured on said hollow shaft; and a cross-head below said rim-mold sustained by rods upwardly slidable in said second cross-head, and adapted to fit and form an annular cover for a blank-mold, and a blank-mold supported on said table and adjusted to receive said neck-mold and plunger, of wrist-bearing wheels below said table having connecting-rods running through said table to move said upper cross-head, and a motor attached to said table to move said wrist-bearing wheels, substantially as shown and described.

3. In a machine of the class designated the combination with the table and blank-mold supported thereon with vertical guides and a cross-head bearing on adjustable hollow shaft secured in a second lower cross-head, and a shaft vertically movable within the hollow shaft, spring-pressed at the top and bearing a plunger at the lower end adapted to enter the blank-mold; and a rim-mold including said plunger sustained from a plate adjustably secured to the hollow shaft above said second cross-head by rods free to slide in said plate, and bearing-springs to press said rim-mold, and a neck-mold adapted to fit said blank-mold, and sustained by rods arranged to slide in said second cross-head, of two wrist-bearing wheels journaled on a shaft below said table, one whereof has gear-teeth; connecting-rods from said wrist to said upper cross-head, a power-shaft counter to said wrist-bearing shaft having a free gear to engage the wrist-bearing gear-wheel, clutch mechanism to cause said free gear to run with its shaft, and a device upon said opposite wrist-bearing wheel to release said clutch mechanism at a predetermined time, substantially as shown and described.

4. In a machine of the class designated the combination with a supporting-table having vertical guides and a cross-head adapted to slide therein, with a hollow shaft adjustably secured therein, and a second cross-head running in said guides secured to the lower end of said hollow shaft bearing a plunger; a downwardly spring-pressed rim-mold surrounding said plunger supported from a plate secured on the hollow shaft, and a vertically-sliding neck-mold supported from said second cross-head of a sliding plate arranged to bring a blank-mold in alignment with said plunger, and a motor arranged by suitable connections to reciprocate said first cross-head, substantially as shown and described.

5. In a machine of the class designated the combination with a supporting-table of a vertically-reciprocating plunger and means for operating it, a sliding plate arranged to hold the blank-mold, and separable blow-mold and to bring them successively under said plunger with an opening in said table to permit the descent of the blow-mold, and an upwardly-pressed vertically-moving plate to receive and hold said blow-mold, and on a lifting-arm arranged to be swung into coincidence with the blow-mold by the movement of said plate, having a flat portion to rest on the jar in the blow-mold, and a valve arranged to be engaged and opened by the descent of the plunger, and to close as it recedes, and means for returning said arm, and mechanism for causing said several parts to meet, substantially as shown and described.

6. In a machine of the class designated the combination with a reciprocating plunger having a determinate vertical stroke, of a table having an opening adapted to be brought in vertical alignment with said plunger, and a vertically-moving depressible upwardly-pressed plate within said opening, a blow-mold adapted to rest on said plate, on a lifting-arm adapted to swing above and close said blow-mold, and means for swinging it, a valve in said arm arranged to be engaged and opened by the descent of said plunger, said arm being arranged to descend and rise with said mold and plunger, and means for returning said arm, substantially as shown and described.

7. In a machine of the class designated the combination with a table and a way thereon for a sliding plate, and diverging grooves in the face of said table, of a sliding plate arranged to move therein provided with a separable blow-mold with the halves hinged at one side, and plate depending from the base thereof through slots in said plate and adapted to run in said grooves, to open and close said mold as said plate slides back or forward, substantially as shown and described.

697,916. SUPPLEMENT. JEREMIAH F. HADLEY, ALTON, Ohio. Filed Nov. 7, 1901. Serial No. 61,801. (No model.)

Claim.—1. In suspension, the combination with the shoulder-strap, a girlo-strap or cord connected therewith in front, and a rear strap, of a suitable connection between the lower extremity of the shoulder-strap in the rear, the girlo-strap and the rear strap, said connection comprising a bifurcated part 7 having two separated bearings for the girlo-strap, and a loop through which the girlo-strap passes between the separated bearings, substantially as described.

2. In suspension, the combination with the shoulder-strap, a girlo-strap or cord connected therewith in front, and a rear strap, of a bifurcated part, a loop 6 connecting the bifurcated part with the shoulder-strap in the rear and provided with two separated bearings which the

girlo-strap or cord engage, and a loop 12 connecting the rear strap with the girlo-strap or cord between the bearings of the bifurcated part.

3. In suspension, the combination with a continuous shoulder-strap part, a loop 6 in the rear through which the said part passes and in which it is movable, a rear strap and a girlo-strap or cord, of a bifurcated part connected with the said loop 6 and having two separated bearings which the girlo-strap engages, and a loop 12 connecting the girlo-strap between the said bearings with the rear strap, substantially as described.

697,917. MANUFACTURE OF GOLF-BALLS. BRADEN KEMPWALL, Boston, Mass., assignor to The Kempwall Manufacturing Company, a Corporation of New Jersey. Filed Nov. 21, 1901. Serial No. 61,802. (No model.)

Claim.—1. The process of making playing-balls, consisting in winding twice or the like around a nucleus of elastic material, causing an inherent tendency permanently maintains said envelope in a state of tension.

2. The process of making playing-balls, consisting of winding several layers of twice or the like around a filling of gutta-percha, applying cement to the twice, making spherical colloidal segments, pressing the segments together over the prepared filling so as to compress the same, and making the edges of the segments.

3. The process of making playing-balls, consisting of winding several layers of twice or the like around a filling of gutta-percha, applying colloidal compound to the twice, making spherical colloidal segments, subjecting them to heat, pressing them together over the prepared filling so as to compress the same, and making the edges of the segments.

4. The herein-described process of making playing-balls, consisting of compressing a coat of twice or three times material over a filling of gutta-percha or the like, causing a colloidal compound or its equivalent to permeate said coat, drying said compound, and compressing heated colloidal shell-sections over the coated filling, substantially as set forth.

697,918. GOLF-BALL. BRADEN KEMPWALL, Boston, Mass., assignor to The Kempwall Manufacturing Company, a Corporation of New Jersey. Filed Jan. 2, 1902. Serial No. 61,804. (No model.)

Claim.—1. A playing-ball comprising a shell built up from lap-jointed sections, and a filling held under compression by said shell, the

material of the lap at the joint between said sections forming a head or web around the interior of the shell.

2. A playing-ball comprising a shell built up of lap-jointed sections of stiff, springy material, and a filling of elastic material held under compression by said shell, said sections being welded together, and the material of the lap forming a head or web which crosses the filling.

3. A playing-ball comprising hemispherical lap-jointed segments of colloidal welded and compressed, and a filling of elastic material held under compression by said shell, the material of the lap forming an interior web or head upon said shell.

4. A playing-ball comprising a colloidal shell made in lap-jointed segments welded together, and a filling consisting wholly or largely of gutta-percha held under compression by said shell; the material of the lap at said joint or web forming a web or head upon the interior of the shell.

697,919. GOLF-BALL. BRADEN KEMPWALL, Boston, Mass., assignor to The Kempwall Manufacturing Company, a Corporation of New Jersey. Filed Jan. 20, 1902. Serial No. 61,805. (No model.)

Claim.—1. A ball consisting of a spherical envelope of solid rubber cured upon a compressible radiant core, which by its inherent expansive tendency permanently maintains said envelope in a state of tension.

2. A ball consisting of a solid rubber envelope cured upon a gutta-percha sphere, which by its inherent expansive tendency constantly stretches said envelope.

697,920. GOLF-BALL. BRADEN KEMPWALL, Boston, Mass., assignor to The Kempwall Manufacturing Company, a Corporation of New Jersey. Filed Mar. 12, 1902. Serial No. 61,806. (No model.)

Claim.—1. A playing-ball comprising a highly-compressed substantial gutta-percha shell expanded by plastic material injected thereto and forming a core, the shell constantly tending to compress the core and the latter to expand the shell.

2. A playing-ball comprising a highly-compressed substantial gutta-percha shell distended by gutta-percha injected thereto.

3. A playing-ball comprising a gutta-percha shell consisting of joined segments, and distended by gutta-percha injected thereto.

4. A playing-ball consisting of a highly-compressed shell built up from compressed gutta-percha segments, said segments being connected edge to edge, and said shell being expanded by gutta-percha forced thereto.

5. A playing-ball comprising a shell built up of highly collidized or compressed thick hemispherical sections of well-cured gutta-percha, said shell being expanded by suitable material injected thereto.

6. A playing-ball comprising a highly-compressed gutta-percha shell distended by gutta-percha injected thereto and forming a core; the diameter of said core being about one-half that of the complete ball.

7. A playing-ball comprising a shell formed at least partially from plastic material and distended by similar plastic material injected thereto.

8. A playing-ball comprising a highly-compressed, substantial gutta-percha shell, and a sphere of gutta-percha held under permanent compression by said shell.

697,921. GOLF-BALL. BRADEN KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 12, 1902. Serial No. 97,886. (No model.)

Claim.—1. In a playing-ball, the combination of a gutta-percha sphere, a soft-rubber bag distended thereon, and a hard, wear-resisting shell upon said rubber and gutta-percha; said rubber bag having sufficient elasticity and a mouth of sufficient size to permit the insertion of said sphere bodily therethrough.

2. A playing-ball comprising a spherical gutta-percha core, a plurality of soft-rubber envelopes or bags drawn over said core, one envelope including another, and each of said envelopes being in a state of expansion, and a hard, wear-resisting shell formed from plastic material and compressed upon said envelopes.

3. A playing-ball comprising a spherical gutta-percha core, a hard shell, and a plurality of rubber bags or envelopes drawn over said core and compressed between the latter and said shell; the mouth of one envelope being closed or reinforced by the body of another.

4. In a playing-ball, the combination of a hard sphere, a soft-rubber bag distended thereon, and a shell consisting at least partially of celluloid and compressed upon said rubber and sphere; said rubber bag having sufficient elasticity and a mouth of sufficient size to permit the insertion of said sphere bodily therethrough.

5. In a playing-ball, the combination of a hard sphere, a soft-rubber bag distended thereon, and a shell consisting at least partially of celluloid; said rubber bag having sufficient elasticity and a mouth of sufficient size to permit the insertion of said sphere bodily therethrough, and said shell being formed from spherical segments which are welded together at their edges.

6. In a playing-ball, the combination of a hard sphere, a soft-rubber bag distended thereon, a disk of rubber closing the mouth of said bag, and a hard, wear-resisting shell formed from plastic material and compressed upon said rubber and gutta-percha; said rubber bag having sufficient elasticity and a mouth of sufficient size to permit the insertion of said sphere bodily therethrough.

7. A playing-ball comprising a spherical gutta-percha core, a hard shell, a plurality of rubber bags upon said core and compressed between the latter and said shell, and a disk closing the mouth of each of said bags; the body of one envelope overlying the mouth of another.

8. A playing-ball comprising a hard core and a succession of complete soft-rubber envelopes including said core.

9. A playing-ball comprising a hard core, a succession of complete soft-rubber envelopes including said core, and a hard shell upon said envelopes, said shell holding said envelopes and core under compression.

10. A playing-ball comprising a hard core formed from plastic material, a plurality of complete rubber envelopes upon said core, and a hard shell formed from plastic material.

697,922. GOLF-BALL. BRADEN KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 12, 1902. Serial No. 97,885. (No model.)

Claim.—1. A playing-ball comprising a gutta-percha shell consisting of welded segments, and a solid sphere consisting entirely of gutta-percha filling said shell and held under compression thereby.

2. A playing-ball consisting of a highly-compressed shell built up from gutta-percha segments, said segments being welded edge to edge, and a filling consisting of gutta-percha powerfully gripped by said shell.

3. A playing-ball comprising a shell built up of highly solidified or compressed thick hemispherical sections of well-cured gutta-percha, and a sphere of highly-compressed gutta-percha held under compression by said shell.

4. A playing-ball comprising a highly-compressed substantial gutta-percha shell and a sphere of highly-compressed gutta-percha powerfully gripped by said shell; the diameter of said sphere being about one-half that of the complete ball.

697,923. GOLF-BALL. BRADEN KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 12, 1902. Serial No. 97,884. (No model.)

Claim.—1. A playing-ball including a core and a shell holding said core under compression, said shell consisting largely or wholly of compressed gutta-percha whose internal strains due to other causes than the expansive tendency of said core have been substantially eliminated.

2. A playing-ball including a core of soft rubber and a shell holding said core under compression, said shell consisting of compressed gutta-percha whose internal strains due to other causes than the expansive tendency of said core have been substantially eliminated.

3. A playing-ball comprising a shell and a solid sphere of well vulcanized soft rubber held under compression by said shell, the latter consisting of welded segments of compressed gutta-percha from which the internal strains due to other causes than the expansive tendency of said sphere have been substantially eliminated.

4. A playing-ball comprising a shell and a sphere of springy material held under compression thereby; said shell being built up of hemispherical sections welded edge to edge, and said sections consisting of gutta-percha from which the internal strains due to other causes than the expansive tendency of said sphere have been substantially eliminated.

5. A playing-ball comprising a substantial shell and a sphere of softer springy material gripped thereby; said shell consisting of compressed gutta-percha whose internal strains due to other causes than the expansive tendency of said sphere have been substantially eliminated.

6. A playing-ball consisting at least partially of a compressed gutta-percha sphere whose internal strains have been substantially eliminated.

697,924. GOLF-BALL. BRADEN KIMBALL, Boston, Mass., assignor to The Kimball Manufacturing Company, a Corporation of New Jersey. Filed Mar. 12, 1902. Serial No. 97,874. (No model.)

Claim.—1. In a playing-ball, the combination with a springy core of a shell cemented thereto and formed of a single pair of welded segments each consisting of two layers, each of said layers consisting of hard, springy material reinforced by tough material.

2. In a playing-ball, the combination with a sphere of rubber of a shell consisting of a single pair of hemispherical segments each consisting of two layers of celluloid interiorly faced with cloth, the inner layer being cemented to said rubber sphere, and the latter being held under compression by said shell.

3. A playing-ball consisting of a yielding core upon which is cemented a closely-compressed thin shell consisting of a single pair of multiple-ply celluloid and fabric segments, each faced upon its inner side with fabric.

4. In a playing-ball, the combination with a core of springy material of a single pair of hemispherical cover-segments welded at their edges and holding said core under compression; each segment comprising an inner layer of woven fabric, a layer of celluloid, as 21, a second layer of woven fabric, and a second layer of celluloid.

5. In a playing-ball, the combination with a core of a single pair of spherical segments, each comprising two layers of woven fabric, as 22, and two layers of celluloid, as 21; said segments being welded at their edges and cemented upon the core.

6. In a playing-ball, the combination of a core and a shell compressed thereon and consisting of an outer ply of well-cured celluloid, then a ply

of fabric, then a second ply of celluloid, and then a second ply of fabric, the latter being cemented to said core.

7. In a playing-ball, the combination with a spherical core consisting at least partially of soft rubber of a shell thereon consisting of a ply of woven fabric next to said core, a ply of celluloid, a second ply of woven fabric, and a second ply of celluloid, the latter forming the outer surface of the ball.

897,925. BILLIARD-BALL. HERMAN KIMMEL, Boston, Mass., assignor to The Kimmell Manufacturing Company, a Corporation of New Jersey. Filed Mar. 24, 1908. Serial No. 88,718. (No model.)

Claim.—1. A playing-ball, comprising an inner and an outer sphere, whereof one has integral ribs which penetrate the other.

2. A playing-ball, comprising an inner and an outer sphere; one of said spheres being harder than the other, and one of said spheres having integral ribs which penetrate the other.

3. A playing-ball, comprising an inner and outer sphere whereof one is harder than the other, said harder sphere having ribs which penetrate the softer sphere.

4. A playing-ball, comprising inner and outer spheres, said outer sphere having inwardly-projecting integral ribs which penetrate the inner sphere.

5. A playing-ball, comprising inner and outer spheres, whereof one has integral ribs and the other has corresponding pits, said ribs extending into said pits and locking the spheres together.

6. A playing-ball, comprising an inner soft sphere provided with pits, and an outer hard sphere provided with ribs which engage said pits.

7. A playing-ball, comprising an inner sphere of rubber and an outer sphere of celluloid, one of said spheres having ribs and the other of said spheres having pits engaged by said ribs.

8. A playing-ball, comprising an inner rubber sphere having pits and an outer celluloid sphere having ribs which project into said pits.

9. A playing-ball, having a hard core, a sphere upon said core, and a shell upon said sphere, one of said sphere and shell elements having integral ribs which penetrate the other of said elements.

10. A playing-ball, comprising a hard core, a soft sphere thereon provided with pits and a hard shell upon said sphere, said shell having integral ribs which enter said pits.

11. A playing-ball, comprising a hollow metal sphere, a rubber envelop thereon, provided with pits and a celluloid shell upon said envelop, said shell having ribs which enter said pits.

12. A playing-ball, comprising a hard core, a soft envelop thereon and a hard shell interlocking with said envelop.

13. A playing-ball comprising a hard core, a soft-rubber envelop thereon and a celluloid shell interlocking with said envelop.

14. A playing-ball, comprising an inner soft sphere provided with pits, and an outer hard sphere compressed thereon and provided with ribs which engage said pits.

15. A playing-ball, comprising an inner sphere of rubber and an outer sphere of celluloid compressed thereon, one of said spheres having ribs and the other of said spheres having pits engaged by said ribs.

16. A playing-ball, comprising an inner rubber sphere having pits and an outer celluloid sphere compressed thereon and having ribs which project into said pits.

17. A playing-ball, having a hard core, a soft sphere upon said core, and a hard shell compressed upon said sphere, one of said sphere and shell elements having ribs which penetrate the other of said elements.

18. A playing-ball, comprising a hard core, a soft sphere thereon provided with pits and a hard shell compressed upon said sphere, said shell having ribs which enter said pits.

19. A playing-ball, comprising a hollow metal sphere, a rubber envelop thereon, provided with pits and a celluloid shell upon said envelop and holding the same under compression, said shell having ribs which enter said pits.

20. A playing-ball, comprising a hard core, a soft envelop thereon and a hard shell interlocking with said envelop and holding it under compression.

21. A playing-ball, comprising a hard core, a soft-rubber envelop thereon and a celluloid shell interlocking with said envelop and holding the same under compression.

22. In a playing-ball, an indented springy sphere and a hard shell interlocked with and maintaining said sphere under compression.

23. In a playing-ball, a rubber sphere uniformly ragged throughout its surface and a hard envelop interlocked with and maintaining said sphere under compression.

24. In a playing-ball, a resilient sphere uniformly ragged throughout its surface and a pyroxylin-composition envelop interlocked with and maintaining said sphere under compression.

25. In a playing-ball, a resilient sphere uniformly ragged throughout its surface and a celluloid envelop interlocked with and maintaining said sphere under compression.

26. In a playing-ball, a springy sphere and a hard shell thereon said sphere and shell being interlocked.

27. In a playing-ball, a hard core, a hard shell and a cushion held under compression between said core and shell and interlocked with the latter.

28. In a playing-ball, a hard hollow core, a hard shell, and a cushion held under compression between said core and shell and interlocked with the latter.

29. In a playing-ball, the combination of a metallic core, a celluloid shell, and a resilient cushion held under compression between said core and shell and interlocking with the latter.

897,926. GOLF-BALL. FRANK H. EDWARDS, Hartford, Conn., assignor to The Kimmell Manufacturing Company, a Corporation of New Jersey. Filed Feb. 28, 1908. Serial No. 88,588. (No model.)

Claim.—1. A playing-ball comprising a filling and a shell of celluloid thereon, said shell having a series of holes.

2. A playing-ball comprising a springy filling and a shell consisting largely or wholly of celluloid, said shell having numerous scattered perforations.

3. A playing-ball comprising a springy filling and a shell consisting largely or wholly of celluloid and holding said filling under compression, said shell having numerous scattered perforations.

897,927. GOLF-BALL. FRANK H. EDWARDS, Hartford, Conn., assignor to The Kimmell Manufacturing Company, a Corporation of New Jersey. Filed Mar. 2, 1908. Serial No. 87,987. (No model.)

Claim.—1. A ball comprising an integral hollow rubber sphere in a state of expansion upon a solid core, and a gutta-percha shell compressed upon said sphere.

2. A ball comprising an integral sphere of rubber expanded over a solid and relatively hard filling formed from plastic material, and a gutta-percha shell holding said sphere under compression.

3. A ball consisting of a whole thick spherical india-rubber sphere in a state of expansion over a solid sphere of gutta-percha, and a gutta-percha shell.

4. A ball comprising a whole sphere of firm india-rubber in a state of expansion over a solid sphere of gutta-percha, the diameter of the core being more than one-half that of said sphere, and a gutta-percha shell compressed upon said sphere.

5. A ball comprising an integral sphere of soft, elastic material expanded upon a solid core of gutta-percha, and a shell formed largely or wholly of gutta-percha and holding said sphere under compression.

6. A ball comprising a solid spherical gutta-percha core, a highly-vulcanized solid soft-rubber envelop expanded thereon, and a shell consisting at least partially of gutta-percha and gripping said envelop.

7. A ball consisting of a core formed of plastic material within a softer elastic sphere and holding the latter under tension, and a shell

formed at least partially of gutta-percha and holding said sphere under compression.

8. A ball consisting of a thick, spherical india-rubber envelop A^1 stretched over a core of gutta-percha E and having an opening closed by a plug B , and a gutta-percha shell upon said envelop.

9. In a playing-ball, the combination of a spherical cut-rubber shell inflated or distended by a mobile mass injected thereto, and a cover or casing of compressed gutta-percha upon said cut-rubber shell.

10. In a playing-ball, the combination of a spherical shell formed of springy material and inflated or distended by gutta-percha injected thereto, and a casing formed of gutta-percha compressed upon said springy shell.

11. In a playing-ball, the combination of a springy shell inflated or distended by springy material injected thereto, one of said shell and injected-material elements being harder than the other, and a casing of gutta-percha compressed upon said shell.

12. In a playing-ball, the combination of a seamless springy shell inflated or distended by springy material injected thereto, one of said shell and injected-material elements being harder than the other, and a casing formed of segments of gutta-percha and welded and compressed upon said shell.

13. In a playing-ball, the combination of a springy shell inflated or distended by springy material injected thereto, said shell being softer than said injected material, and a casing formed of compressed gutta-percha and holding the latter under compression.

14. In a playing-ball, the combination of a seamless rubber shell expanded by gutta-percha injected thereto, and a casing formed of gutta-percha upon said rubber shell.

15. In a playing-ball, the combination of a spherical shell formed of springy material and inflated or distended by gutta-percha injected thereto, and a casing formed of spherical segments of gutta-percha welded at their edges and compressed upon said spherical shell.

16. In a playing-ball, the combination of a shell formed of springy material and inflated or distended by springy mobile material injected thereto, and a casing consisting of at least partially of gutta-percha and holding said springy shell under compression.

17. In a playing-ball, the combination of a seamless springy shell inflated or distended by springy material injected thereto, one of said shell and injected-material elements being harder than the other, and a casing of gutta-percha holding said seamless shell under compression.

18. In a playing-ball, the combination of a springy shell inflated or distended by springy material injected thereto, said shell being softer than said injected material, and a casing consisting of welded segments holding said shell under compression; said casing consisting largely or wholly of gutta-percha.

19. In a playing-ball, the combination of a seamless rubber shell expanded by gutta-percha injected thereto, and a gutta-percha casing compressed upon said shell and holding the latter under compression.

20. A playing-ball comprising a solid spherical envelop expanded upon a core and a casing of compressed gutta-percha upon said envelop.

21. In a playing-ball, the combination of a filling consisting of a spherical envelop of cut material expanded upon a solid sphere and a shell consisting of compressed segments of gutta-percha and holding said filling under compression.

22. A playing-ball comprising a solid cut spherical envelop expanded upon a solid sphere of gutta-percha, and a shell formed of gutta-percha and compressed upon said envelop.

23. A ball comprising an integral hollow rubber sphere in a state of expansion upon a hollow core, and a gutta-percha shell compressed upon said sphere, the diameter of said core being substantially two-thirds the diameter of said sphere, and said sphere having substantially eighty-five per cent. of the diameter of said shell.

897,998. MOTOR CONTROLLING APPARATUS. GRAYVILLE T. WOOD and LYMAN WOOD, New York, N. Y., assignors, by direct and mesne assignments, to Henry C. Townsend and Robert H. Decker, trustees. Filed Sept. 2, 1901. Serial No. 74,595. (No model.)

Claim.—1. In a system of motor control, the combination of a driving-motor, an electrical armature in series therewith, an electromagnetic field-magnet for said armature, a motor-switch in circuit with said field and adapted to control the same, and a commutating-switch, which, when manually operated, causes said motor-switch or controller to change the resistance of said field-circuit.

2. In a system of motor control, the combination of a driving-motor, an electrical armature in series therewith, an electromagnetic field-magnet for said armature, a motor-switch in circuit with said field and adapted to vary and reverse said field, and a commutating-switch which, when operated manually, is adapted to cause said motor-switch to vary and reverse said field.

3. In a system of motor control, the combination of a driving-motor, an electrical armature in series therewith, an electromagnetic field-magnet for said armature, a motor-switch in circuit with said field and adapted to control the same, a commutating-switch in circuit with said motor-switch and adapted to control the same, and means adapted to reverse the driving-motor.

4. In a system of motor control, the combination of a driving-motor, an electrical armature in series therewith, an electromagnetic field-magnet for said armature, a motor-switch in circuit with said field and adapted to vary and reverse said field, a commutating-switch in circuit with said motor-switch and adapted to control the same, and means adapted to reverse said driving-motor.

5. In a system of motor control, the combination of a driving-motor, a generator-armature in series therewith, a field-magnet for said armature, a motor-switch in circuit with said field and adapted to control the same, and an automatically-acting device in circuit with said driving-motor and adapted to move under the influence of an abnormal current and thereby interrupt the supply of said current to damage said driving-motor.

6. In a system of electrical control, the combination of a driving-motor, a generator-armature in series therewith, a field-magnet for said armature, a motor-switch having a stop-by-stop motion and adapted to control said field, a commutating-switch in circuit with said motor-switch and adapted to control the motion of the same, and means for reversing the driving-motor.

7. In a system of electrical control, the combination of a driving-motor, a generator-armature in series therewith, a field-magnet for said armature, a motor-switch in circuit with said field and adapted to control the same, a commutating-switch in circuit with said motor-switch and adapted to control the motion thereof, and a switch in the field-circuit of said driving-motor and adapted to reverse the same.

8. In an electrical system, the combination of a driving-motor, a controller divided into sections, a commutating-switch adapted to energize said controller section by section, and means adapted to check the commutating-switch in its forward movement only when said switch is operated in both directions by hand.

9. In an electrical system, the combination of a driving-motor, a controller apparatus divided into sections, a commutating-switch adapted to energize said apparatus section by section, means adapted to check the movement of the motor-switch, and means adapted to cause said commutating-switch to stand open circuit when the latter is at rest.

10. The combination of a motor, a speed-controller a reversing device for said motor, a commutating-switch, and means adapted to check said commutating-switch in its forward movement only when operated in both directions by hand.

11. The combination of a motor, a speed-controller, a reversing device for said motor, a commutating-switch, and means adapted to check said commutating-switch in its forward movement only when operated in both directions by hand.

12. The combination of a motor, a speed-controller, a motor-reversing device, a single set of wires, and a commutating-switch provided with means to check it in its forward movement only and said switch being adapted to feed energy from said single set of wires to both the said controller and said reversing device.

13. In combination, an electrically-operated car or vehicle, a driving-motor therefor, a controller for said motor, a commutating-switch to govern said controller, and means adapted to act automatically and assist in bringing the car or vehicle to rest when manual control of said commutating-switch ceases.

14. In combination, a plurality of electrically-operated cars adapted to be connected together to form a train, a plurality of driving-motors for each car, a motor-controller upon each car, a commutating-switch adapted to simultaneously control the entire number of said motors, and means adapted to act automatically and assist in bringing the car to rest when manual control of the commutating-switch ceases.

15. In combination, a controller comprising two parts, a fixed contact part and a movable contact part, the appropriate contact or contacts of one part being adapted to have a positive spring-pressure against the appropriate contact or contacts of the other part, a series of actuating devices adapted to move said movable part step by step, a commutating-switch adapted to successively bring said actuating devices into operation, and means adapted to prevent a rapid forward movement of said commutating-switch.

16. In combination, a controller comprising a set of fixed contacts and a set of movable contacts, a series of separately-actuating devices adapted to move said movable set of contacts step by step, through a series of operative positions, means adapted to successively bring said actuating devices into operation, and means adapted to yieldingly press the appropriate contacts of one set against the appropriate contacts of the remaining set.

17. In combination, a controller comprising a set of fixed contacts, and a set of movable contacts, a common support for said movable contacts, a series of separately-actuating devices for moving said set of movable contacts step by step, through a series of operative positions, means adapted to successively bring said actuating devices into operation, and elastic means adapted to press the appropriate contacts of one set against the appropriate contacts of the remaining set.

18. In combination, a controller comprising a set of fixed contacts and a set of movable contacts, a common support for said movable contacts, a series of separately-actuating devices for moving said set of movable contacts step by step, through a series of operative positions, means adapted to successively bring said actuating devices into operation, and means adapted to elastically press the appropriate contacts of one set against the appropriate contacts of the remaining set.

19. In combination, a motor-controller comprising a set of fixed contacts and a set of movable contacts, a common support for said movable contacts, a series of separately-actuating devices for moving said set of movable contacts step by step, through a series of operative positions, means adapted to successively bring said actuating devices into operation, and elastic means adapted to press the appropriate contacts of one set against the appropriate contacts of the remaining set.

20. In combination, a controller comprising a set of fixed contacts and a set of movable contacts, a common support for said movable contacts, a plurality of separately-actuating devices adapted to shift said set of movable contacts through a series of operative positions, each of said actuating devices being adapted to move said support through a portion only of its full movement, a commutating-switch operatively connected to said actuating device, said commutating-switch being constructed and arranged to successively energize said actuating device, and means adapted to yieldingly press the appropriate contacts of one set against the appropriate contacts of the remaining set.

21. In a train system, a plurality of motor-controllers each having a set of fixed contacts and a set of movable contacts, each set of movable contacts being mounted upon a common support, a plurality of separately-actuating devices operatively related to the common support of each controller, each of said devices being adapted to move the said support through a portion only of its full movement, means adapted to connect the said actuating devices in multiple, a commutating-switch connected and arranged to supply current simultaneously to said actuating devices of the several controllers, and means adapted to yieldingly press the appropriate contacts of one set against the appropriate contacts of the remaining set of the several controllers.

22. In a train system, a plurality of motor-controllers each comprising a set of fixed contacts and a set of movable contacts, a plurality of separately-actuating devices, operatively related to the movable contacts of each controller, each of said devices being adapted to move said movable contacts through a portion only of their full movement, a set of conductors extending through the train and to which said actuating devices are connected, a commutating-switch adapted to extend the connection between a source of supply and said conductors to simultaneously move the movable contacts a predetermined distance.

23. In combination, a controller comprising fixed contacts and a movable contact or contacts, the faces of the appropriate contacts being pressed together by a spring-like pressure during their electrical connection, a series of separately-actuating devices adapted to move said movable contact or contacts, and means adapted to deliver energy, successively and at the will of the operator, to any portion of the entire number of said coils.

24. In combination, a controller comprising fixed contacts and movable contacts, a series of separately-actuating devices adapted to move said movable contacts step by step, in one direction only, through a series of operative positions, means adapted to return said movable contacts to their normal position, and means adapted to successively energize said actuating devices.

25. In combination, a controller comprising fixed contacts and movable contacts, a set of actuating-coils adapted to move said movable contacts, and a commutating-switch adapted to deliver current to a circuit which includes a plurality of said actuating-coils less than the total number.

26. In combination, a controller provided with fixed contacts and movable contacts, a set of actuating-coils adapted to control said contacts, and a commutating-switch adapted to deliver current, successively, to a plurality of circuits, each such circuit including a plurality of said actuating-coils less than the total number.

27. In combination, a controller comprising fixed contacts and movable contacts, a set of actuating-coils adapted to actuate said movable contacts, a commutating-switch, a set of separately-energized circuits controlled thereby, each of such circuits containing a plurality of said coils, and a resistance in circuit with a plurality of such coils.

28. In combination, a controller comprising fixed contacts and movable contacts, a set of actuating-coils adapted to operate said movable contacts, a set of separately-energized circuits, each containing a plurality of said coils, and a commutating-switch adapted to deliver energy, at the will of the operator, to a plurality of said coils less than the total number.

29. The combination of a motor, a commutating-switch, and a controller comprising fixed contacts, movable contacts and a set of actuating-coils for operating said movable contacts, the said coils being adapted to receive energy in varying amounts, each coil causing the appropriate change in the contact connections upon each coil receives its proper proportion of the current.

30. The combination of an electric motor, a controller therefor, a commutating-switch to govern said controller, a source of supply for said motor, and a regulating device in series with the armature of said motor and acting to vary the electromotive force of the current delivered from said source of supply to said motor.

31. The combination of an electric motor, a controller therefor, a commutating-switch to govern said controller, a source of supply for said motor, and an inductive regulating device in series with the armature of said motor and acting to vary the electromotive force of the current delivered from said source of supply to said motor.

32. The combination of an electric motor, a controller therefor, a commutating-switch to govern said controller, a regulating-armature in series with the armature of said motor, and means adapted to drive said regulating-armature.

33. The combination of an electric motor, a controller therefor, a commutating-switch to govern said controller, a regulating-armature in series with the armature of said motor, and means adapted to reverse said motor.

34. The combination of an electric motor, a controller therefor, a commutating-switch to govern said controller, a regulating-armature in series with the armature of said motor, means adapted to drive said regulating-armature and means adapted to reverse said motor.

35. The combination of an electric motor, a controller therefor, a commutating-switch adapted to cause said controller to move step by step, a regulating-armature in series with the armature of said motor, and electromagnetic means for reversing said motor.

36. A train having a plurality of electrically-equipped cars, a regulating-armature upon each such car and in series with the armature of the car-driving motor, and a commutating-switch adapted to control the operation of the entire plurality of regulating-armatures.

37. A train having a plurality of electrically-equipped cars, a regulating-armature upon each such car and in series with the armature of the car-driving motor, means for reversing said motor and a commutating-switch adapted to control the entire plurality of regulating-armatures whereby the current delivered to said car-driving motors will be proportioned to the work performed by each motor.

38. In combination, a driving-motor, a speed-controller therefor, a commutating-switch and means adapted to vary the current in the motor-field circuit independently of the armature-circuit thereof.

39. In combination, a driving-motor, a speed-controller therefor, a commutating-switch means adapted to reverse said motor, and means adapted to vary the field strength of said motor, independently of the armature circuit thereof.

40. In combination, a driving-motor, a speed-controller therefor, a commutating-switch in circuit with said speed-controller, and means adapted to vary the field strength of said motor, independently of the armature-circuit thereof.

41. In combination, a plurality of driving-motors, having their fields in series with each other, a speed-controller for said motors, means for reversing said fields, and means adapted to vary the strength of said fields independently of the armature-circuits thereof.

42. In combination, a plurality of motors having their fields in series with each other, an electromagnetic device in series with the armature of said motor, and an electrically-operated reversing-switch in circuit with said field.

43. In combination, a plurality of motors, having their fields connected in series with each other, an electromagnetic device in series with the armature of said motor, an electromagnetic reversing-switch in circuit with said fields, and means adapted to control the current which actuates said switch.

44. In combination, a plurality of motors, a speed-controller therefor, an electromagnetic device in series with the armature of said motor, a reversing-switch in circuit with the fields of said motors, and means adapted to actuate said reversing-switch.

45. In combination, a plurality of motors, a speed-controller therefor, a reversing-switch in circuit with the fields of said motors, an electromagnetic device in series with the armatures of said motors, means adapted to prevent sparking during the reversal of said motors, and means adapted to actuate said reversing-switch.

46. In combination, a plurality of motors, a speed-controller therefor, a commutating-switch adapted to actuate said speed-controller, a reversing-switch in circuit with the fields of said motors, an electromagnetic device in series with the armatures of said motors, means adapted to prevent sparking during the reversal of said motors, and means adapted to actuate said reversing-switch.

47. The combination of a motor, a speed-controller, a commutating-switch, and an automatic circuit-controller, the latter controller having two levers which constantly tend to move to open the circuit, one of such levers being held in its normal position by a latch and the other lever is held in its normal position by a magnet.

48. The combination of a motor, a speed-controller, a commutating-switch, an automatic circuit-controller having two levers, one of such levers being held in its normal position by a latch and means adapted to act, upon an excessive flow of current, and release said lever.

49. In combination, a motor, a controller therefor, a spring-controlled commutating-switch adapted to electrically actuate said controller through a series of operative positions, and a spring adapted to return said controller to its normal position.

50. In combination, a motor, a controller therefor, a commutating-switch adapted to govern the controller and means such as a spring constantly tending to restore the controller to its normal position independently of the retrograde movement of the commutating-switch.

51. In combination, a motor, a controller therefor, a commutating-switch adapted to govern said controller, a reversing-switch for said motor, and means such as a spring constantly tending to restore the controller to its normal position independently of the retrograde movement of said commutating-switch.

52. In combination, a motor, a controller therefor, and a commutating-switch adapted to be connected, through the coils of said controller, to a two-point switch, one of the points of the latter switch being connected to a branch circuit in series with the motor, and the remaining switch-point being connected to a circuit in parallel with the motor.

53. In combination, a motor, a motor-controller comprising fixed contacts and movable contacts, a motor-reversing device, a plurality of commutating-switches, a commutating-switch line connected between the latter switches, and a connection between said line and said controller whereby either of the commutating-switches will be enabled to cause said controller to be energized section by section and to move step by step.

54. The combination of a train having a plurality of electrically-equipped cars, each of such equipments having a motor-controller with spring-pressed contacts and a commutating-switch to energize the controller section by section, and means adapted to make a direct electrical connection between the commutating-switch on car and a like device on another car independently of the sequence of the equipped cars.

55. In a system of electrical control, the combination of a driving-motor and its circuits, speed or work controlling apparatus for said motor, a commutating-switch adapted to govern said controlling apparatus, motor-reversing mechanism connected to said motor-circuits, and an independent switch adapted to deliver energy to said reversing mechanism each time the latter is operated, the said mechanism being inactive except during the reversal of said motor.

56. A car provided with a motor, motor-controlling apparatus, a plu-

rality of commutating-switches, and a group of commutating-switch wires, said wires having branches leading to the controlling apparatus, and other branches leading to coupling-heads at each end of the car, all of the wires being connected in said heads in a single vertical or substantially vertical series, the serial number of a given wire connection in one head being a duplicate of such connection in the other head.

57. The combination of a plurality of cars, driving-motors upon each of said cars, controller apparatus for said motors, spring-pressed contacts for such controllers, commutating-switches upon each equipped car and adapted to energize said controller apparatus section by section and means for directly connecting the commutating-switch wires of one car in series with such wires on another car independently of the sequence or order relation of the cars.

58. In a system of electrical control, the combination of a plurality of cars, driving-motors and their circuits upon each of said cars, speed-controlling apparatus upon each motor-equipped car, fixed contacts and movable contacts being included in said speed-controlling apparatus, a commutating-switch adapted to govern all of the speed-controlling apparatus simultaneously, means, such as springs, relating to said movable contacts, whereby the latter contacts constantly tend to open the motor-circuits, and means, such as a spring, located at said commutating-switch whereby all of said movable contacts will be caused to act automatically and open the motor-circuits upon failure of the motorman to control said commutating-switch while actuating-current is being delivered to said motors.

697,989. INSULATING-ROCK. THOMAS S. YOUNG, Fenn, Oreg. Filed Dec. 2, 1901. Serial No. 94,948. (No model.)

Claim.—1. A device substantially as herein described, composed of a rod of metal bent between its ends to form the loop or ring, united immediately adjacent to the said loop or ring and having one extremity bent to form the hook proper, with its end bent outwardly, and the safety-keeper curving laterally outward over the hook proper and extending downwardly to a point outside of and below the plane of the hook proper, substantially as set forth.

2. A device substantially as herein described, provided with the returned hook proper and with a safety-keeper extending from a point adjacent to the shank of the hook laterally across the hook proper and to a point beyond the said hook, substantially as set forth.

3. A device substantially as herein described, comprising the loop or ring, the shank portion extending therefrom, the hook proper and the safety-keeper extending laterally across and to a point beyond the hook proper, substantially as set forth.

4. A device substantially as herein described, comprising the ring or loop, the hook proper and the safety-keeper extending from a point adjacent to the shank of the hook proper and curving thence upwardly and then downwardly to a point above, outside of, and below the hook proper, substantially as set forth.

5. A device substantially as described, composed of a rod of metal bent between its ends to form the ring or loop and at its ends to form the hook proper, and the safety-keeper, substantially as set forth.

697,980. RAIL CHAIR AND INSULATOR. WALTER D. YOUNG, Baltimore, Md. Filed Mar. 5, 1901. Serial No. 48,103. (No model.)

Claim.—1. An appliance of the character described, comprising a casting having means for detachably supporting an insulated rail-chair, and its opposite ends constructed to support guard-rails.

2. An appliance of the character described, comprising a casting, adapted to support a rail-chair, its opposite ends having means to support guard-rails, and members to which said rails can be made fast.

3. An appliance for the purpose stated, having a central upwardly-projecting spindle and vertical end portions, as set forth.

4. An appliance of the character described, having a central hub and a spindle, each 10° at the outer ends and vertical portions 10, having bolt-apertures, for the purpose described.

5. The hereinbefore-described appliance, comprising a member 1, adapted to be spiked to a cross-tie, said member 1, having a spindle 14, each 10°, and vertical flange 10°, and having integral vertical members 10, having bolt-apertures, all being arranged substantially as shown and for the purpose described.

6. A combined rail holder and insulator, comprising a base member adapted to be secured to the cross-tie, a rail holder and support mounted on the base-plate and insulated therefrom, said base-plate having upturned portions provided with seats to receive the guard-rails, substantially as shown and for the purposes described.

7. A third-rail insulator having its base provided with means for supporting a guard-plank.
8. A third-rail insulator having its base provided with extensions adapted to support a guard-plank.
9. A third-rail insulator having on its base extensions provided with one or more flanges to support a guard-plank.
10. A third-rail insulator having on its base an extension provided with a pedestal, and means for securing a guard-plank on said pedestal.
11. A third-rail insulator having on its base an extension provided with a pedestal having one or more flanges to support a guard-plank.
12. A third-rail insulator having a base provided with extensions, pedestals on said extensions, and upright flanges on said pedestals.
13. The combination with a third-rail insulator having lateral extensions on its base, of a guard-plank supported on each extension, and rising above the top of the rail.

697,981. METHOD OF MAKING GAS-PURIFYING AGENTS.
HARRY S. BLACKMON, Mount Vernon, N. Y. Filed Feb. 18, 1891. Serial No. 47,976. (No model.)

- Claim.*—1. The process of making a composition for use in purifying gas which consists in exposing dense or vitreous iron ore to the action of metallic acid and water capable of liberating heat in the mixture by chemical reaction.
2. The process of making a composition for use in purifying gas which consists in exposing a water-insoluble compound, containing iron as principal constituent, to the action of calcium acid and water.
 3. The process of making a composition for use in purifying gas which consists in exposing a broken or comminuted composition, insoluble in water, containing iron acid as principal ingredient, to the action of calcium acid and water.
 4. The process of making a composition for use in purifying gas which consists in pulverizing hematite, mixing the same with pulverized calcium acid, and exposing it to the action of water.
 5. The process of making a composition for use in purifying gas which consists in exposing a refractory ore containing iron to the combined action of calcium acid and water.
 6. The process of making a composition for use in purifying gas which consists in exposing a refractory compound containing iron as principal constituent, to the action of calcium acid and water.

697,982. AUTOMATIC BRIF FOR STEAM-LINES. JAMES H. BLACKLY, Homestead, Pa., assignor of one-half to James H. Blackly, Homestead, Pa. Filed Dec. 16, 1901. Serial No. 22,761. (No model.)

- Claim.*—1. In a steam-line, the combination of a regulating-valve, a mercurial thermostat secured to said regulating-valve, and a hollow valve-stem extending into said mercurial thermostat, substantially as described.
2. In a device of the character described, the combination with a steam-line, a casing, a mercurial thermostat secured in said casing, a regulating-valve comprising a hollow stem extending into said thermostat,

and means whereby said valve is automatically regulated, substantially as described.

3. In a device of the character described, the combination with a steam-line, a casing formed therein, a cup arranged in said casing, a diaphragm secured to the upper and lower sides of said cup, means to regulate the expansion and contraction of said diaphragm, a valve, a hollow stem secured to said valve and extending into said cup and secured to one of said diaphragms, and a spring arranged between said diaphragm and casing, all parts being arranged substantially as described, and for the purpose set forth.

697,988. LOCK. HILDEBRAND E. MATCHLEY, Whitehall, Ill., assignor to H. G. Tuntion, Whitehall, Ill. Filed Jan. 20, 1901. Serial No. 44,893. (No model.)

- Claim.*—1. A device of the class described, comprising a cleave and a latch-lever, the latch-lever including an arm and a stem lying at an angle to the arm, said stem having a portion adapted for engagement with the cleave to hold the stem against rotation, and a portion adapted for rotation in the cleave to permit of movement of the arm into and out of operative position, and a latch carried by one member for engagement with the other member to hold the angular portion in engagement with the cleave.
2. A lock comprising an attaching-plate having a cross-sectionally angular cleave formed therein, and a latch-lever including an arm and a stem lying at an angle to the arm, said stem having a cross-sectionally angular portion adjacent to the arm to fit the cleave and prevent rotation of the arm, and having the remaining portion rounded to permit of rotation of the arm into and out of operative position when the stem is moved with its rounded portion to lie in the cleave, and a latch carried by one member for engagement with the other member to hold the angular portion in engagement with the cleave.
 3. A lock comprising an attaching-plate having a cross-sectionally angular cleave formed therein, and a latch-lever comprising an arm and a stem, said stem having a cross-sectionally angular portion adjacent to the arm to fit the cleave and hold the arm against rotation and having its remaining portion formed for rotation in the cleave, and a spring-catch carried by the arm and projecting normally from the stem to lie against the cleave and prevent displacement of the angular portion of the stem therefrom.
 4. A lock for meeting-rolls of rubber, comprising an attaching-plate having an angular cleave, a second attaching-plate having a beveled stud, and a latch-lever including an arm having a stem projecting at an angle therefrom, said stem having its portion adjacent the arm formed to fit the cleave and prevent rotation therein, and the remaining portion formed to permit of rotation in the cleave, said arm having a beveled lug for engagement with the first-named beveled lug to draw the plates together when the stem is moved slidably to engage the angular portion thereof with the cleave.

697,984. RAILWAY SAFETY-BLOCK SYSTEM. GEORGE W. CURTIS, Allegheny, Pa., assignor of nine-sixteenths to John R. C. Wheeler, Charles L. Stevens, R. A. Sutton, A. Hart McKee, George F. Bock, and Jacob Wolf, Allegheny, Pa., and William C. McElhenny, and George O. Morgan, Pittsburg, Pa. Filed Aug. 3, 1901. Serial No. 71,393. (No model.)

Claim.—1. An electromechanical railway signal system, comprising a plurality of main signal-stands placed along the railway to divide the same into blocks or sections each of which is provided with a pair of oscillable signal-arms, intermediate signal-stands each having a single signal-arm thereon, an indicator-board having indicators thereon representing each block, a miniature oscillable arm on each indicator, means whereby a train on entering the first block will automatically and simultaneously oscillate the signal-arms of the first main stand and its indicator from safety to danger position, means at the terminus of said block whereby the train on leaving the same will automatically and simultaneously oscillate the signal-arms on the intermediate stand therein and the succeeding main stand at the entrance of next block and their respective indicator-arms from safety to danger position, means at the entrance of said block whereby the signal-arms of the first block-stand and its indicator will be automatically restored by the train to their normal or safety position, means at the terminus of the same and each succeeding block whereby the signals of the intermediate stand therein and the succeeding main stand thereof with their respective indicator-arms will be automatically and simultaneously oscillated by the train from safety to danger position, means at the entrance of said last-mentioned and each succeeding block whereby the signal-arms on said intermediate and main stand and their respective indicators will be automatically and simultaneously restored by the train from danger to safety position, and a telephone arranged on said indicator-board and each of said main signal-stands.

2. An electromechanical railway signal system, comprising a plurality of main signal-stands placed along the railway to divide the same into blocks or sections each of which is provided with a pair of oscillable signal-arms, intermediate signal-stands each having a single signal-arm thereon, an indicator-board having indicators thereon representing each block, a miniature oscillable arm on each indicator, means whereby a train on entering the first block will automatically and simultaneously oscillate the signal-arms of the first main stand and its indicator from safety to danger position, means at the terminus of said block whereby the train on leaving the same will automatically and simultaneously oscillate the signal-arms on the intermediate stand therein and the succeeding main stand at the entrance of next block and their respective indicator-arms from safety to danger position, means at the entrance of said block whereby the signal-arms of the first block-stand and its indicator will be automatically restored by the train to their normal or safety position, means at the terminus of the same and each succeeding block whereby the signals of the intermediate stand therein and the succeeding main stand thereof with their respective indicator-arms will be automatically and simultaneously oscillated by the train from safety to danger position, means at the entrance of said last-mentioned and each succeeding block whereby the signal-arms on said intermediate and main stand and their respective indicators will be automatically and simultaneously restored by the train from danger to safety position.

will be automatically restored by the train to their normal or safety position, means at the terminus of the same and each succeeding block whereby the signals of the intermediate stand therein and the succeeding main stand thereof with their respective indicator-arms will be automatically and simultaneously oscillated by the train from safety to danger position, and means at the entrance of said last-mentioned and each succeeding block whereby the signal-arms on said intermediate and main stand and their respective indicators will be automatically and simultaneously restored by the train from danger to safety position, and means at said indicator-board whereby the signals controlling each block may be separately operated therefrom to danger or safety position independent of the train-actuating means.

3. An electromechanical railway signal system, comprising a plurality of main signal-stands placed along the railway to divide the same into blocks or sections each of which is provided with a pair of oscillable signal-arms, intermediate signal-stands each having a single signal-arm thereon, an indicator-board having indicators thereon representing each block, a miniature oscillable arm on each indicator, means whereby a train on entering the first block will automatically and simultaneously oscillate the signal-arms of the first main stand and its indicator from safety to danger position, means at the terminus of said block whereby the train on leaving the same will automatically and simultaneously oscillate the signal-arms on the intermediate stand therein and the succeeding main stand at the entrance of next block and their respective indicator-arms from safety to danger position, means at the entrance of said block whereby the signal-arms of the first block-stand and its indicator will be automatically restored by the train to their normal or safety position, means at the terminus of the same and each succeeding block whereby the signals of the intermediate stand therein and the succeeding main stand thereof with their respective indicator-arms will be automatically and simultaneously oscillated by the train from safety to danger position, means at the entrance of said last-mentioned and each succeeding block whereby the signal-arms on said intermediate and main stand and their respective indicators will be automatically and simultaneously restored by the train from danger to safety position, and a telephone arranged on said indicator-board and each of said main signal-stands.

4. An electromechanical railway signal system comprising a plurality of main signal-stands placed along the railway to divide the same into blocks or sections each of which is provided with a pair of oscillable signal-arms, intermediate signal-stands each having a single signal-arm thereon, an indicator-board having indicators thereon representing each block, a miniature oscillable arm on each indicator, means whereby a train on entering the first block will automatically and simultaneously oscillate the signal-arms of the first main stand and its indicator from safety to danger position, means at the terminus of said block whereby the train on leaving the same will automatically and simultaneously oscillate the signal-arms on the intermediate stand therein and the succeeding main stand at the entrance of next block and their respective indicator-arms from safety to danger position, means at the entrance of said block whereby the signal-arms of the first block-stand and its indicator will be automatically restored by the train to their normal or safety position, means at the terminus of the same and each succeeding block whereby the signals of the intermediate stand therein and the succeeding main stand thereof with their respective indicator-arms will be automatically and simultaneously oscillated by the train from safety to danger position, means at the entrance of said last-mentioned and each succeeding block whereby the signal-arms on said intermediate and main stand and their respective indicators will be automatically and simultaneously restored by the train from danger to safety position, means at said indicator-board whereby the signals controlling each block may be separately operated therefrom to danger or safety position independent of the train-actuating means, and a telephone arranged on said indicator-board and each of said main signal-stands.

5. An electromechanical-operated block-signal system, a signal-stand, comprising a stand, a pair of oscillable signal-arms mounted on one side thereof which are positioned at right angles to one another, a pulley or drum mounted thereon, a chain extending from said drum to a crank on each of said arms, a weight suspended from said drum to rotate the same in one direction, a core suspended from said drum, and a solenoid-magnet arranged in said stand which when energized is adapted to act upon said core and rotate said drum in an opposite direction to reverse the positions of said signal-arms.

6. In an electromechanical-operated block-signal system, an intermediate block-stand, comprising a stand, a vertical oscillable signal-arm mounted upon one side thereof, a pulley or drum arranged thereon, a chain connecting said signal-arm with said drum, a core suspended from said drum, and a solenoid-magnet in said stand which is adapted when energized to act upon said core and rotate said drum to rotate said signal-arm to a horizontal position.

7. In an electromechanical block-signal system, a circuit-closer, comprising a casing, a horizontal shaft extending therefrom having cranks rigidly fixed at its outer and inner end, a vertical chamber on said casing, a piston-plunger in said chamber connected to said inner crank and normally opened by spring-pressure, and means in said chamber whereby a circuit is closed by the downward movement of said plunger when said outer crank is depressed.

8. In an electromechanical railway signal system, a train-actuated circuit-closer, comprising a chamber, a piston-plunger operatively arranged in said chamber, a crank-lever adapted to engage with and be depressed by the wheels of a train, a pump connecting said lever with the plunger to move the latter in one direction when depressed, circuit-closing members in said chamber and insulated therefrom which are adapted to be brought into engagement by said plunger when so moved, and means for restoring said plunger and crank to their normal position.

9. In an electromechanical railway signal system, a train-actuated circuit-closer, comprising a chamber, a piston-plunger operatively arranged in said chamber, a crank-lever adapted to engage with and be depressed by the wheels of a train, means connecting said lever with the plunger to move the latter in one direction when depressed, circuit-closing members in said chamber and insulated therefrom which are adapted to be brought into engagement by said plunger when so moved, means for restoring said plunger and crank to their normal positions, and means carried by one of said circuit members whereby engagement of the plunger therewith may be adjusted.

10. In an electromechanical semaphore-signal system operated by the train, the combination therewith, of indicating devices representing said semaphores, and means whereby said devices will automatically and simultaneously indicate the positions assumed by said semaphores.

11. In an electromechanical semaphore-signal system operated by the train, the combination therewith, of oscillable indicators representing said semaphores, and means whereby said indicators will automatically and simultaneously oscillate to positions assumed by said semaphores.

12. In an electromechanical semaphore-signal system operated by the train, the combination therewith, of indicating devices representing said semaphores, means whereby said devices will automatically and simultaneously indicate the positions assumed by said semaphores, and means independent of that actuated by the train for separately actuating any one of said semaphores and its indicator.

13. In an electromechanical semaphore-signal system operated by the train, the combination therewith, of oscillable indicators representing said semaphores, means whereby said indicators will automatically and simultaneously oscillate to positions assumed by said semaphores, and means independent of that actuated by the train for separately actuating any one of said semaphores and its indicator.

14. In a railway signal system, the combination of a signal-circuit having a make-and-break mechanism therein, a second circuit having therein a train-actuating circuit-closer and a mechanism to operate the make-and-break mechanism of said signal-circuit when closed by the train, means to automatically lock said make-and-break mechanism in the position assumed at closure of said second circuit, and a third circuit having therein a train-actuating circuit-closer and a mechanism to act upon and release said lock when closed by the train to effect a restoration of said signal-circuit.

15. In a railway signal system, the combination of a signal-circuit having a make-and-break mechanism therein, a second circuit having therein a train-actuating circuit-closer and a mechanism to act upon and bring together the make-and-break members of said signal-circuit when closed by the train, means to automatically lock said make-and-break members when brought together at closure of said second circuit, and a third circuit having therein a train-actuating circuit-closer and means for acting upon and releasing said lock when closed by the train to effect a restoration of said signal-circuit.

16. In a railway signal system, the combination of a signal-circuit having therein a signal on indicator therefor and a make-and-break mechanism, a second circuit having therein a train-actuating circuit-closer and a mechanism to operate the make-and-break mechanism of said signal-circuit when closed by the train, means to automatically lock said make-and-break mechanism in the position assumed at closure of said second circuit, and a third circuit having therein a train-actuating circuit-closer and a mechanism to act upon and release said lock when closed by the train to effect a restoration of the signal and its indicator.

17. In a railway signal system, the combination of a signal-circuit having therein a signal on indicator therefor and a make-and-break mechanism, a second circuit having therein a train-actuating circuit-closer and a mechanism to act upon and bring together the make-and-break members of said signal-circuit when closed by the train, means to automatically lock said make-and-break members when brought together at closure of said second circuit, and a third circuit having therein a train-actuating circuit-closer and means for acting upon and releasing said lock when

closed by the train to effect a restoration of the signal and its indicator.

18. In a railway signal system, the combination of a signal-circuit having therein a signal on indicator therefor and a make-and-break mechanism, a second circuit having therein a train-actuating circuit-closer and a mechanism to operate the make-and-break mechanism of said signal-circuit when closed by the train, means to automatically lock said make-and-break mechanism in the position assumed at closure of said second circuit, a third circuit having therein a train-actuating circuit-closer and a mechanism to act upon and release said lock when closed by the train to effect a restoration of the signal and its indicator, and means independent of that operated by the train to operate said signal and indicator.

19. In a railway signal system, the combination of a signal-circuit having therein a signal on indicator therefor and a make-and-break mechanism, a second circuit having therein a train-actuating circuit-closer and a mechanism to act upon and bring together the make-and-break members of said signal-circuit when closed by the train, means to automatically lock said make-and-break members when brought together at closure of said second circuit, and a third circuit having therein a train-actuating circuit-closer and means for acting upon and releasing said lock when closed by the train to effect a restoration of the signal and its indicator, and means independent of that operated by the train to operate said signal and indicator.

20. In a railway signal system, the combination of a circuit having a signal and a make-and-break mechanism therein, a second circuit having therein a train-actuating circuit-closer and a mechanism to operate the make-and-break mechanism of said signal-circuit when closed by the train, means to automatically lock said make-and-break mechanism in the position assumed at closure of said second circuit, a third circuit having therein a train-actuating circuit-closer and a mechanism to act upon and release said lock when closed by the train to effect a restoration of said signal, and means independent of that operated by the train for operating said signal.

697,985. PLURAL-POSS OUT-OUT. CHARLES J. DORSEY, Baltimore, Md., assignor, by direct and mesne assignments, to Ames Press Box Company. Filed Nov. 23, 1902. Renewed Sept. 5, 1901. Serial No. 74,399. (No model.)

Claim.—1. In a plural-poss out-out, a series of parallel insulated bars, a series of insulated conducting blocks each adapted to be put in an electric circuit with a fuse, and a rotatable circuit-closing device having a path tangential to each block, said blocks being of unequal lengths and comprising parts that are curved to surround the circuit-closing device and prevent fuses in the path of said device.

2. A series of fuses adapted to be successively put in an electric circuit, a fuse-box comprising parts separable near the plane of the fuses, a circuit-closer adapted to be electrically connected with each fuse in turn, said closer comprising a rotatable ratchet and a corresponding fixed ratchet, the latter being fixed in one part of the box and the other carried by the other part of the same.

3. A series of fuses adapted to be successively put in an electric circuit,

coil, a two-box comprising parts separable near the plane of the frame, a circuit-closer adapted to be electrically connected with each line in turn, said closer comprising a movable ratchet and a corresponding fixed ratchet, the latter being fixed in one part of the box and the other carried by the other part of the same, a ratchet-operating key, and a spring pressing the ratchets together, said spring and key being carried with the same separable part of the box that carries the movable ratchet.

4. A series of fuses adapted to be successively put in an electric circuit, a two-box comprising parts separable near the plane of the frame, a circuit-closer adapted to be electrically connected with each fuse in turn, a series of conducting-blocks in the path of the circuit-closer, each of said blocks being provided with a groove, means for connecting a fuse to each block, and non-conducting ribs adapted to enter the grooves, the blocks being situated in one part of the box and the ribs in the other, and the ribs extended transversely through a plane passing between the parts.

697,986. HICKY-BAND FASTENER. WILLIAM S. DUNBAR, Brooklyn, N. Y., assignor of one-half to the E. J. Manville Machine Company, Waterbury, Conn., a Corporation of Connecticut. Filed Nov. 12, 1900. Serial No. 36,578. (No model.)

Claim.—A hicky-band fastener bent to shape from a single piece of metal and having a shank with loops, a curved guard extending forwardly from the shank and a tongue with a forwardly-projecting point extending between the loops of the shank to the curved guard and provided with a hump whereby the point may be pressed out of the guard-loop, substantially as specified.

697,987. TROLLEY-WIRE HANGER. RAO L. BOWARD, Aurora, Ill., assignor of two-thirds to Spencer A. Sanders, Louis M. Cota, and Aurelio Cota, Aurora, Ill. Filed Jan. 29, 1900. Serial No. 31,882. (No model.)

Claim.—1. A trolley-wire hanger having shiftable means for engaging a stringer-wire comprising a bar having hooks, a slotted screw-threaded stud, and a nut on the stud to directly engage the stringer-wire, the hooks and slot in the stud being in alignment whereby bending or kinking of the wire is obviated, substantially as described.

2. A trolley-wire hanger having shiftable means for engaging a stringer-wire comprising a bar having hooks, a slotted stud screw-threaded, and a nut on the stud, and having a shiftable trolley-wire clamp, substantially as described.

3. A trolley-wire hanger having a trolley-wire clamp comprising a fixed and a movable member, a screw to draw them together, a lug on one member to enter an opening in the other, and means to limit the separation of said members at a point before the lug becomes freed from the opening, substantially as described.

4. A trolley-wire hanger having an insulator-cup and a trolley-wire clamp secured to the cup by nuts and threaded posts, said clamp having a movable member adapted to engage one of the nuts to limit the separation of the movable member from the other member, substantially as and for the purpose described.

5. In a trolley-wire hanger, the combination of an insulator-cup, a trolley-wire engaging part, posts and nuts connecting the latter and the cup, and washers seated in cavities in the nuts, substantially as described.

697,988. LOCKING DEVICE. CHARLES B. FOSTER, JR., Cincinnati, Ohio, assignor of one-half to Walter Macleod, Newport, Ky. Filed Oct. 2, 1901. Serial No. 77,578. (No model.)

Claim.—1. A locking device consisting of two complementary parts, one being a keeper and the other a bolt carried on a base-plate, a guiding-lug 24 projecting from one of the edges of the base-plate, the one nearest the keeper when the parts are in position, guides 15 projecting from near the other edge of the base-plate, a bolt supported between these three projecting parts in a manner to be free for manual movement in two directions, one being between guides 15 near its rear or inner end

and from the base-plate to lying the outer end of the bolt opposite the keeper, the other movement being in a direction lengthwise of the base-plate for the purpose of entering the keeper from the position found by the first movement and when the bolt is aligned therewith, and a cam pivotally supported between the outer ends of guides 15 closing the space therebetween them, and serving in its operative position to hold the bolt on the base-plate in any of its positions in which it has found and engaged the keeper.

2. A locking device consisting of a bolt and a complementary keeper, a base-plate, guides between which this bolt is received to the base-plate in a manner to have a limited movement to and from this latter and also one in a longitudinal direction to engage the keeper out of any position due to its first movement, a lip 27 at the front end of the bolt, a projection at the rear end thereof and a pivotally-supported cam adapted to rest upon this latter projection on the bolt after the same has engaged its keeper, thereby causing a reverse longitudinal movement of the bolt for the purpose of drawing the complementary parts of the lock together.

697,989. SAME-TIGHTENING DEVICE. CHARLES B. FOSTER, JR., Cincinnati, Ohio. Filed Oct. 12, 1901. Serial No. 78,085. (No model.)

Claim.—1. In a nut-tightening device, the combination of two complementary parts of which one is to be secured to the nut so as to move therewith, and the other is a stationary portion adjacent thereto, one of the parts being a pivotally-supported pawl having also a bodily movement toward or from the other part and in a direction at right angles to the plane of the nut and the guide-ribs thereof and the other part having two projections of which one, when coming in contact with the pawl, causes the same to tilt, while the other returns it again to its normal position, and a spring to yieldingly impel the movement of the pawl toward the other part.

2. In a nut-tightening device, the combination of two complementary parts, of which one is a pawl having a slot, a pin received by this latter and on which the pawl is supported to have a tilting motion, a housing within which this supporting-pin is secured, a spring also in the housing in contact with the inner end of the pawl and with a normal tendency to push the same outwardly on the pin occupying its slot toward the other part which latter has two projections of unequal extent and whereby when the two parts pass each other, the longer projection is capable of tilting the pawl to bring it in contact with the other part, while the shorter projection, when passing in reverse direction, returns it again into its former position, in which it remains, leaving the nut free to move in either direction without coming in contact with the stationary part.

3. In a nut-tightening device, the combination of two complementary parts, one being a pivotally-supported pawl having also a bodily movement to or from the other part, which latter has two projections of unequal extent adapted to engage the pawl to tilt it either toward and in contact with each other part or away therefrom, a spring to hold each pawl in the former controlling position and means to positively lock it in each position.

697,940. WRENCH. SAMUEL A. HAINES, Carroll, Tex., assignor to William H. Spahn, Anaheim, Cal. Filed Apr. 3, 1901. Serial No. 34,181. (No model.)

Claim.—An adjustable wrench comprising an angular socket portion adapted to extend partially within the wheel-hub to engage the nut, an integral handle extending from the socket portion at an angle to the axis thereof, said socket portion having two rearwardly-extended oppositely-disposed walls forming spaced pivot-cams, jaws pivoted between the cam at points within the exterior face of said socket portion, the inner flat faces of said jaws being adapted to fit snugly against the exterior wall

of the socket member to parallel the curvature of the wheel while a small wheel-hub and the outer face of said jaws being rounded for engagement with the inner wall of the hub, transversely-extended operating-levers for said jaws, and a ring disposed upon the handle for engagement with the corrugations to hold said jaws in an adjusted position, substantially as specified.

697,941. GAS-FIRE APPLIANCE. JOSEPH F. HEWITT, Allegheny, Pa. Filed July 22, 1900. Serial No. 754,788. (No model.)

Claim.—1. A gas-burner comprising a hollow body formed of refractory material and metallic gauze or mesh, the refractory material forming the front being supported by the gauze or mesh and having numerous minute perforations formed therein through the interstices of the gauze.

2. A gas-burner comprising a number of intercommunicating bodies formed of refractory material and metallic gauze or mesh, the refractory material forming the front thereof being supported by the gauze or mesh and having numerous minute perforations therein through the interstices of the gauze.

697,942. SPEECH-HOLDER. JOHN H. REEDER, New York, N. Y., assignor of one-half to Clarence F. Curley, Brooklyn, N. Y. Filed Feb. 7, 1900. Serial No. 69,908. (No model.)

Claim.—A speech-holder comprising a back plate, rows of spaced pins projecting from the back plate to receive and carry the speech, a hook-bar of spring metal made approximately U-shaped and having end flanges, one of which is pivoted on the back plate, and the other is formed with an aperture and projects below the end of the back plate, and a pin on the back plate, adapted to be engaged by the said aperture and flange, to hold the hook-bar against side-to-side swinging movement, as set forth.

697,943. METAL SHEET-PIPING. GEORGE W. JAMISON, Chicago, Ill., assignor to the International Steel Piping Company, Chicago, Ill., a Corporation of Illinois. Filed Mar. 24, 1901. Serial No. 27,788. (No model.)

Claim.—1. Metallic sheet-piping consisting of metal beams provided on their adjacent side margins with distal ends partially closed, looped flanges, one of said flanges being bent so as to extend laterally from and backwardly upon the web of the beam and then inwardly with its free edge directed toward and terminating in a distance from the adjacent face of the said web, and the other flange being bent or folded so as to extend laterally from the plane of the beam, then in the direction of said plane and then inwardly toward the same and having its free edge directed outwardly parallel with the inwardly-directed portion, so as to form thereon a marginal groove, said flanges being so constructed that the corresponding portions thereof have close-fitting contact with each other and the inwardly-directed edge of the first-mentioned flange fits within the said groove of the second one.

2. The combination with a pile structure embracing a plurality of metal beams which have interlocking edges adapted for connection and separation of the beams by relative endwise movement thereof, of supporting-brackets adapted for detachable connection with the beams.

3. The combination with a pile structure embracing a plurality of metal beams which have interlocking edges adapted for connection and separation of the beams by relative endwise movement thereof, of a blocking-web, and supporting-brackets adapted for detachable connection with the beams to which said web is affixed.

4. The combination with a piling-section, of a web-supporting bracket and a plate which is attached permanently to said section and with which said bracket is adapted for detachable engagement.

5. The combination with a piling-section of a bracket-supporting plate adapted to be permanently attached to said section and a bracket which is adapted for detachable connection with said plate.

6. The combination with a piling-section of a bracket-supporting plate having an upwardly-opening socket at its upper end and a seat at its lower end, and a bracket having an upper downwardly-directed end to engage said socket, and a lower end adapted to engage said seat.

697,944. CRANK-SHAFT BEARING OF MOTOR. FRANKLIN J. JENNISON, Philadelphia, Mass. Filed Jan. 24, 1900. Serial No. 2,007. (No model.)

Claim.—1. In a crank-shaft bearing, the combination with the barrel of the crank-shaft provided with a slot, of a sleeve adapted to receive the crank-shaft, a pair of eccentric rings attached to the ends of said sleeve, a thick eccentric ring attached to the central portion of said sleeve, said eccentric rings fitting the barrel of the crank-shaft, a stud projecting radially from said central ring through the slot in said barrel and a clamping-nut carried by said stud by which the sleeve is held from rotation in said barrel, substantially as described.

2. In a crank-shaft bearing, the combination with the barrel of the crank-shaft provided with a slot, of a sleeve adapted to receive the crank-shaft consisting of a piece of tubing and having braced or colored eccentric rings fitting said barrel, with a screw-threaded stud projecting radially from one of said rings through said slot and a clamping-nut carried by said stud, substantially as described.

697,945. RUNNING-GEAR FOR MOTOR-VEHICLES. HARRY A. KINK and JAMES H. JONES, Springfield, Mass., assignors to Kink Automobile Company, Springfield, Mass., a Corporation. Filed Nov. 24, 1901. Serial No. 69,112. (No model.)

Claim.—1. A running-gear for motor-vehicles consisting of a pair of axles, two springs constituting the rear ends of said gear, supports on said axles for the ends of the springs, and a rigid arm secured by one end to one of the springs near the center of the latter and extending to one of said axles and having a pivotal connection therewith.

2. A running-gear for motor-vehicles consisting of a front and a rear axle, two springs, supports for the opposite ends of said springs, respectively, on said axles, one end of one of said springs having both a rotation and a sliding movement to its support.

8. A running-gear for motor-vehicles consisting of a front and a rear axle, two springs, supports for their opposite ends respectively on said front and rear axles, and both ends of each spring having a relative movement in their supports.

4. A running-gear for motor-vehicles consisting of a front and a rear axle, two springs, supports for their opposite ends respectively on said front and rear axles, both ends of each spring having a relative movement in their supports on the axles, and one end of each spring having in addition a sliding movement therein.

5. A running-gear for motor-vehicles consisting of a front and rear axle, two springs, supports for the opposite ends of said springs, respectively, on said axle, one end of one of said springs having both a relative and a sliding movement relative to one of said axles.

6. A running-gear for motor-vehicles consisting of a front and a rear axle, two springs, supports for their opposite ends respectively on said front and rear axles, both ends of each spring having a relative movement in their supports on the axles, and one end of one spring having in addition a sliding movement therein.

7. A running-gear for motor-vehicles consisting of a front and a rear axle, two springs, supports for their opposite ends, respectively, on said front and rear axle, said springs constituting the members of the gear, the ends of said springs on the front axle having a relative movement relative to each other.

8. A running-gear for motor-vehicles consisting of a pair of axles, two springs, constituting members, extending between the axles, a driving-shaft for the driving-axle mounted on said springs, parallel with said driving-axle, a rigid connection between the latter and said shaft, and a yielding connection between said axle and said springs, whereby the flexure of the latter may take place without varying the distance between the said shaft and the axle driven thereby.

697,946. FURNACE FOR CRYSTALLIZING OR INCRYSTALLIZING HUMAN BONES. HENRY C. EYMER, HENGE Village, N. Y., assignor to Crystallizing Company of New York, New York, N. Y., a Corporation of New York. Filed Mar. 10, 1901. Serial No. 61,899. (No model.)

Claim.—1. A crystallizing-furnace, comprising a structure forming a crematory-chamber closed at one end, a combustion-chamber located at the other end of the crematory-chamber, a support located in the crematory-chamber at a distance above its bottom and spaced from the side thereof, a passage leading from the combustion-chamber to the crematory-chamber below said support at the end of the crematory-chamber opposite to its closed end; and an outlet-flue leading from the crematory-chamber above said support at the same end at which the said passage is located, whereby the combustion-gases will be caused to enter the crematory-

chamber below the support, pass around the substance to be cremated, and back over the substance into the flue.

2. A crystallizing-furnace, comprising a structure forming a combustion-chamber and a crematory-chamber the inlet of which communicates with the outlet of the combustion-chamber, and an outlet-flue leading from the crematory-chamber through the combustion-chamber, said flue leading directly from the crematory-chamber and having imperforate walls from the outlet of the crematory-chamber to a point beyond the combustion-chamber, so that the cremation products will not pass through the combustion-chamber on their way from the crematory-chamber to the outlet-flue.

697,947. CAR-JOURNAL BOX. THOMAS W. MITCHELL, Omaha, Neb. Filed Sept. 2, 1901. Serial No. 74,705. (No model.)

Claim.—The combination with the box having the tight but removable cover and elongated opening in its rear face for the entry of the journal whereby the box and journal may move laterally with respect to each other, of a hard-metal disk, working against the face of the box and movable transversely with the journal, a packing-ring resting against the disk and having inwardly-projecting soft-metal flat-faced segments, a follower bearing against the packing-ring to advance said ring and disk toward the box, whereby side wear will occur only between the hard-metal disk and rear face of the box, both passing loosely through eyes on the follower and box whereby the follower and ring may partake of the transverse movements of the disk and journal and springs surrounding the bolts for advancing the follower; substantially as described.

697,948. MILLING APPARATUS. WILLIAM E. MCGILVER, Hopkinton, Mass., assignor to Sprague Company, Portland, Me., and Hope Falls, Mass. Filed Oct. 3, 1901. Serial No. 71,046. (No model.)

Claim.—In milling apparatus, drag and cope flasks, a pattern-frame to rest upon the drag-flask and contain the cope-flask during the construction of the cope, and stops projecting beyond the opposed portions of the flasks and cooperating with each other when the pattern-frame is interposed, said stops also cooperating with each other after removal of the said frame, to equalize and positively control the pressure between the parting faces of the mold.

697,949.

697,949. METAL WAGON-BODY. WILLIAM E. SHAWFIELD, Chicago, Ill. Filed July 19, 1901. Serial No. 66,971. (No model.)

Claim.—1. As a new article of manufacture, a wagon-body having its sides, bottom and ends formed from sheet-metal plates, the sides having corrugations therein arranged in panels and in ornamental design, and the bottom having corrugations extending throughout its length, and yokes each formed of a single flanged bar bent to embrace said sides and bottom and secured thereto, substantially in the manner and for the purpose set forth.

2. As a new article of manufacture, a wagon-body having its bottom and ends formed from sheet-metal plates, and having sides formed of two sheet-metal plates, the outer plate having corrugations therein, and the inner plate being plain, and the corrugations being arranged in panels of ornamental design, and yokes, each formed of a single flanged bar bent to embrace said sides and bottom and secured thereto, substantially as set forth.

3. As a new article of manufacture, a wagon-body having its bottom and ends formed from sheet-metal plates, sides formed from two plates spaced apart, the inner plate being plain, and the outer plate being corrugated, a stiffening backing or filling arranged between said side plates, and metal yokes embracing said sides, and bottom and secured thereto, substantially as described.

4. As a new article of manufacture, a wagon-body composed of sheet-metal sides, bottom and ends, said sides having corrugations therein, and said bottom being reinforced by a corrugated metal plate, and yokes embracing the sides and bottom, substantially as set forth.

5. A wagon-body composed of sheet-metal sides, bottom and ends, the sides formed of two plates, the outer one of which has corrugations formed therein, and the bottom formed of two plates, the lower one of which is corrugated and supports the upper one, and yokes embracing the sides and bottom, substantially as described.

6. As a new article of manufacture, a wagon-body having ends, sides and bottom formed from sheet-metal plates, yokes formed of flanged metal bars embracing said sides and bottom and secured thereto, metal channel-bars extending longitudinally under the bottom plate, other channel-bars extending transversely under the bottom plate, and vertical channel-bars embracing the side plates and secured to the transverse channel-bars, as described.

7. In a wagon having sides, bottom and ends formed of sheet-metal plates, yokes embracing the sides and bottom, said yokes formed of bent-metal channel-bars extending transversely under the bottom and projecting on each side thereof, and vertical channel-bars secured to said horizontal bars and embracing the sides of the wagon-body, sliding-rings secured to said vertical bars, and levers secured to said vertical and horizontal bars.

8. In a wagon, having sides, bottom and ends formed of sheet-metal plates, a sheathing-board formed by extending the side and bottom plates beyond the tail-gate or rear end of the wagon-body, and flanged bars extending longitudinally under said bottom and its extension, to support same.

9. In a wagon, a bottom formed of two metal plates spaced apart with wooden bars interposed therebetween, and flanged metal bars extending longitudinally, and other flanged metal bars extending transversely under said bottom, as set forth.

697,950. METAL WHEEL. WILLIAM E. SHAWFIELD, Chicago, Ill. Filed July 19, 1901. Serial No. 66,972. (No model.)

Claim.—1. In a wheel, a metal hub-ring of the resilient character described, having a series of depressions in its face adapted to form half-

vertical seats or bearings for spokes, the portions between said depressions being plane or sub-plane.

2. In a wheel, a metal hub-ring of the resilient character described, having inwardly-curved depressions in its face said depressions adapted to fit the bent portion of U-shape spokes.

3. In a wheel, a metal hub-ring of the compressible or resilient character described, having a series of curved depressions in its face, said depressions being of maximum depth at their centers and gradually diminishing toward each end, for the purpose described.

4. In a wheel, a resilient metal hub-ring having curved spoke-seats formed therein by stamping inwardly portions of the ring substantially as set forth.

697,951. METAL TONGUE FOR VEHICLES. WILLIAM E. SHAWFIELD, Chicago, Ill. Filed Dec. 26, 1901. Serial No. 67,165. (No model.)

Claim.—1. A wagon-tongue composed of two metal T-bars secured together, and having their side flanges curved inwardly for a portion of their length, and straight or normal for the rest of their length, said straight portion being at the rear end of the tongue.

2. A wagon-tongue composed of two metal T-bars secured together, and having their side flanges extending normally at the rear portion of the tongue, and gradually curving into curved flanges, the latter occupying the rest of the tongue, substantially as set forth.

3. A wagon-tongue composed of two metal T-bars secured together with gradually-varying space therebetween, the greatest space being toward the rear portion of the tongue, whereby the tongue is given a tapering contour, the flanges of said bars being curved inwardly for a portion of their length.

tion of their length, and left normal for the rest of their length, the radii of said curved portions gradually increasing from the front end of the tongue toward the rear portion, substantially in the manner shown.

4. As a new article of manufacture, a wagon-tongue formed of two complementary metal bars, secured together with a space therebetween for a portion of their length, and forming, when joined, a metal tongue having its rear portion rectangular in cross-section, and its forward portion rounded and tapering substantially in the manner and for the purpose set forth.

697,952. METAL RUNNING-CHAR FOR WAGONS. WILLIAM H. SCHOFIELD, Chicago, Ill. Filed Dec. 28, 1891. Serial No. 57,154. (No model.)

Claim.—1. In a running-char for wagons, the combination of a transverse axle composed of two flanged conical sections formed from sheet metal and secured together, a bolster composed of flanged metal bars supported by the axle, and metal standards having portions secured to and embraced by the bars forming the bolster.

2. In a running-char for wagons, the combination of a tubular axle composed of two flanged conical sections formed from sheet metal and secured together at their flanges, a bolster composed of flanged metal bars, each secured in the axle and to the bolster, and metal standards having portions secured to and embraced by the metal bars forming the bolster.

3. In a running-char for wagons, the combination of a tubular axle composed of two flanged conical sections formed from sheet metal and secured together at their flanges, a bolster formed of flanged metal bars having outwardly-turned flanges, each secured to the axle and the bolster, and standards having portions secured to and embraced by the metal bars composing the bolster.

4. In a running-char for wagons, a metal standard composed of a flat metal bar, a horizontal foot at the lower end of said bar, a vertical extension below said foot and at right angles to said bar, and a vertical rib extending from the top of the bar to the foot, said bar, foot, extension and rib all integrally formed, substantially as set forth.

5. In a running-char for wagons, a bolster formed of two complementary flanged metal bars secured together with a space therebetween and with their flanges outward, substantially as described.

6. In a running-char for wagons, an axle composed of two flanged conical sections formed from sheet-metal plates and secured together at their flanges, and having extensions at each end of the axle, said extensions being without flanges.

7. In a running-char for wagons, an axle composed of two flanged conical sections formed from sheet-metal plates and secured together at their flanges, and having end portions without flanges and having the edges of said end portions not secured, and metal sleeves fitting over said end portions and forming spindle-bearings, substantially as described.

8. In a running-char for wagons, an axle composed of two conical sections formed from sheet-metal plates, secured together at their flanges and having end portions without flanges, metal sleeves fitting said end portions of the axle, and means for preventing said sleeves from turning and from longitudinal displacement.

9. In a running-char for wagons, an axle composed of two conical sections formed from sheet-metal plates secured together at their flanges and having unflanged end portions, metal sleeves fitting said end portions, said sleeves having a rib formed thereon and slide out thereon, and rings fitting over said sleeves and secured to the flanges of the axle.

697,953. KNITTING-MACHINE. ROBERT W. SMITH, Philadelphia. LOUIS E. D. WILLIAMS, ALEXANDER, and HARRY SWINDELMAN, Philadelphia, Pa., assignors to said Smith and Williams. Filed Sept. 4, 1891. Serial No. 74,307. (No model.)

Claim.—1. The combination of the cam-shaft of the machine, a pattern-chain wheel loosely mounted thereon, a pair of ratchet-wheels, one connected to the cam-shaft and the other to the pattern-chain wheel, a device operated by the cam-shaft ratchet-wheel for controlling the action of the pawl which operates the pattern-chain ratchet-wheel, and a device operated by the pattern-chain ratchet-wheel whereby said cam-shaft and pattern-chain are operated alternately, substantially as specified.

2. The combination of the cam-shaft of the machine, a pattern-chain wheel loosely mounted thereon, a pair of ratchet-wheels one connected to the cam-shaft and the other to the pattern-chain wheel, said cam-shaft ratchet-wheel having a stop-tooth formation, a device operated by the cam-shaft ratchet-wheel for controlling the action of the pawl which operates the pattern-chain ratchet-wheel, and a device operated by the pattern-chain ratchet-wheel whereby said cam-shaft and pattern-chain are operated alternately, substantially as specified.

3. The combination of the cam-shaft of the machine, a ratchet-wheel connected thereto, a pattern-chain wheel mounted loosely in respect to the cam-shaft, a ratchet-wheel connected to said pattern-chain wheel, a cam on the cam-shaft ratchet-wheel for moving into and out of action the pawl which operates the ratchet-wheel of the pattern-chain, a lever for controlling the operation of the pawl which acts upon the cam-shaft ratchet-wheel, and a leg on the pattern-chain for operating said lever, substantially as specified.

4. The combination of the cam-shaft of the machine, a ratchet-wheel connected thereto and having a stop-tooth formation, a pattern-chain wheel mounted loosely in respect to the cam-shaft, a ratchet-wheel connected to

said pattern-chain wheel, a device operated by the cam-shaft ratchet-wheel, a cam on the cam-shaft ratchet-wheel for moving into and out of action the pawl which operates the ratchet-wheel of the pattern-chain, a lever for controlling the operation of the pawl which acts upon the cam-shaft ratchet-wheel, and a leg on the pattern-chain for operating said lever, substantially as specified.

5. The combination of the cam-shaft, the pattern-chain wheel, ratchet-wheel and pawl mechanism for independently and alternately operating said parts, a disk on the cam-shaft having groups of ratchet-teeth of various pitch than those of the cam-shaft ratchet-wheel, and a reciprocating pawl for acting upon said teeth of the disk, substantially as specified.

6. The combination of the pattern mechanism having a ratchet and pawl, the pawl-operating rock-shaft and its arm and the knitting-head adapted to be reciprocated by a swinging segment having a portion for engaging said arm, the termination of the arm when the latter reaches a predetermined point in its throw being circular and of the same radius as the path of the engaging portion of the segment whereby the arm is moved by the latter only up to a certain point in its swing, substantially as specified.

7. The combination of the cam-cylinder of the machine and its knitting-cams, with a supplementary lift or down-down cam, a radially-guided slide carrying the same, and having a normal tendency to move in one direction, and a retaining-trigger therefor, said slide and trigger being in different horizontal planes whereby they may be operated by different adjustments of a single disk or tappet, substantially as specified.

8. The combination of the needle-cylinder having some needles with short butts and some with long butts, the cam-cylinder and its knitting-cams, the supplementary lift-cam, the slide thereby guided to move in a plane transverse to the movement of the needles, and means for retaining said slide in two different positions of adjustment in advance of the position of rest whereby, when retracted, it will not act upon any of the needles, when partially projected, it will operate only the long-butted needles, and, when fully projected, it will operate also the short-butted needles, substantially as specified.

9. The combination of the needle-cylinder having some needles with long butts and others with short butts, the cam-cylinder and its knitting-cams, a supplementary lift-cam, a radially-guided slide carrying the same and having a normal tendency to move in one direction, and a spring-trigger for retaining said slide, said trigger having two notches whereby it is adapted to retain the slide in a partially-projected position, and also in a fully-projected position, substantially as specified.

10. The combination with the needle-cylinder having some needles with long butts and others with short butts, the cam-cylinder and its knitting-cams, a supplementary lift-cam, a radially-guided slide carrying the same and having a normal tendency to move in one direction, means for retaining said slide in different positions of adjustment, and two independent disks or surfaces for causing projection of the slide, one of said disks or surfaces moving the slide to a greater distance than the other, substantially as specified.

11. The combination of a supplementary cam of the cam-cylinder, a radially-guided slide carrying the same, and a locking device for said slide, with a control-disk, and means for operating the same, comprising a rotated cam-disk, and a rock-shaft with two arms, one acted upon by the cam of said disk and the other acting upon the stem or spindle of the control-disk, substantially as specified.

12. The combination of the cam-cylinder of the machine, with needle-lifting pickers and needle-depressing pickers independently mounted upon said cam-cylinder but having frictional driving contact therewith whereby they are caused to move in the plane of the cylinder, and independent cams, one for raising the lifting-picker and the other for lowering the depressing-picker, substantially as specified.

13. The combination of the cam-cylinder of the machine, with needle-lifting pickers and needle-depressing pickers independently mounted upon said cam-cylinder but having frictional driving contact therewith whereby they are caused to move in the plane of the cylinder, and independent cams, one for raising the lifting-picker and the other for lowering the depressing-picker, substantially as specified.

14. The combination of the cam-cylinder of the machine, with needle-lifting pickers and needle-depressing pickers independently mounted upon said cam-cylinder but having frictional driving contact therewith whereby they are caused to move in the plane of the cylinder, and independent cams for operating said lifting and depressing pickers, each of said cams having a stripper-cam for continuing and completing the partial movement imparted to the needle by the picker, substantially as specified.

15. The combination of the cam-cylinder with a needle-picker mounted thereon so as to be free to move independently thereof but having frictional driving contact with the cylinder whereby it is caused to move in the plane of the cylinder, and means for preventing rebound of the picker when it strikes the butt of a needle, substantially as specified.

16. The combination of the cam-cylinder with a needle-picker

mounted thereon so as to have movement independently thereof but having frictional driving contact with the cylinder whereby it is caused to move in the plane of the cylinder, and a spring-actuated retainer for preventing rebound of the picker when it strikes the butt of a needle, substantially as specified.

17. The combination of the cam-cylinder with a needle-picker mounted thereon so as to have movement independently thereof but having frictional driving contact with the cylinder whereby it is caused to move in the plane of the cylinder, and a spring-actuated retainer for preventing rebound of the picker when it strikes the butt of a needle, and holding said picker in contact with said needle-butt with a yielding pressure, substantially as specified.

18. The combination of the cam-cylinder with a needle-picker mounted thereon so as to be capable of movement independently thereof but having frictional driving contact with the cylinder whereby it is caused to move in the plane of the cylinder, and one or more yielding retainers acting to hold said picker in its intermediate position, substantially as specified.

19. The combination of the cam-cylinder with a needle-picker mounted thereon so as to be capable of movement independently thereof, and yielding retainers for holding said picker in its intermediate and opposite extreme positions, substantially as specified.

20. The combination of the cam-cylinder with a needle-picker mounted thereon so as to be free to move independently thereof, and a spring-actuated lever mounted so as to be tripped when the needle-picker approaches either limit of its movement and then acting to retain said picker in such position, substantially as specified.

21. The combination of the cam-cylinder and a needle-picker mounted thereon, so as to have movement independently thereof, a pair of levers acting to retain the picker in either of its opposite positions, a spring connecting said levers, and shoulders to limit the approach of the levers under the action of the spring, substantially as specified.

22. The combination of the cam-cylinder with a needle-picker mounted thereon so as to be capable of movement independently thereof, a lever mounted so as to be tripped as the needle-picker approaches the limit of its movement, and a spring-actuated arm bearing upon said lever on opposite sides of the fulcrum of the same so as to retain it in a central position or permit movement of the same in either direction from such central position, substantially as specified.

23. The combination of the cam-cylinder of the machine, with a picker-carrier mounted thereon so as to be capable of movement independently thereof, and a spring-actuated shoe bearing upon said picker-carrier when it is in its intermediate position so as to yieldingly retain it in that position, substantially as specified.

24. The combination of the cam-cylinder of the machine with a needle-picker carrier mounted so as to be capable of movement thereon, a cam for operating said picker, and means for moving the picker-carrier in one direction or the other on each occasion when the picker has been moved out of engagement with the butt of a needle, substantially as specified.

25. The combination of the cam-cylinder of the machine with a needle-picker carrier mounted so as to be capable of movement thereon, a cam for operating said picker, and yieldingly-mounted buffers for moving the picker-carrier in one direction or the other after the picker has been moved out of engagement with the butt of a needle, substantially as specified.

26. The combination of the cam-cylinder of the machine, picker-carrier thereon, one carrying a lifting-picker and the other a depressing-picker, cams for operating the said pickers, buffers, one for the lifting-picker carrier and the other for the depressing-picker carrier, and means for moving said buffers into and out of operative position, substantially as specified.

27. The combination of the cam-cylinder of the machine, picker-carrier thereon, one carrying a lifting-picker and the other a depressing-picker, cams for operating the said pickers, buffers, one for the lifting-picker carrier and the other for the depressing-picker carrier, and means for moving said buffers first into position to act upon the lifting-picker carrier, then into position to act upon the depressing-picker carrier, and then to a neutral or inoperative position, substantially as specified.

28. The combination of the cam-cylinder of the machine and its picker-carrier, opposite buffers for engagement with said picker-carrier, a yoke carrying said buffers, and means for reciprocating said yoke, substantially as specified.

29. The combination of the needle-cylinder of the machine and its needles, means for raising the needles so that all of their butts will be in the same horizontal plane, means for raising the needle-cylinder independently of the needles, and a retaining-disk for engaging with the butts of the needles and preventing rise of the same by reason of their frictional contact with the needle-cylinder, substantially as specified.

30. The combination of the needle-cylinder of the machine, its needles and the knitting-cams, with a needle-cylinder support, and means for

gradually lowering the same so as to vary the length of the stitches, said means comprising a cylinder-supporting lever, a shaft with cam for acting upon said lever, a rock-shaft having an arm for controlling the position of said lever when it is free from the control of the cam, and a pattern-chain acting upon another arm on said rock-shaft and having legs of different size for imparting successive movements to said rock-shaft, substantially as specified.

31. The combination of the needle-cylinder and its needles, the knitting-cams, and needle-cylinder support, a lever acting thereon, a cam acting upon said lever, and a controlling device for the lever independent of the cam, said device comprising an arm having an eccentric hook engaging a projection on the lever and a pattern device for operating said cam, substantially as specified.

32. The combination of the needle-cylinder and its needles, the knitting-cams, the needle-cylinder support, the lever acting thereon, the cam acting on said lever, a rock-shaft having two arms, one for controlling the movement of the lever independently of the cam, and a pattern-chain having legs for acting upon the other arm of the rock-shaft, substantially as specified.

697,954. RECTANGULAR OR TANK. ROBERT P. STEWART, Paris, Tex., assignor of one-half to William E. Hagan, Paris, Tex. Filed Oct. 14, 1901. Serial No. 73,573. (No model.)

Claim.—1. That method of producing an underground receptacle which consists in first applying a layer of hot asphaltum to the surface of a tank and permitting said layer to stand until it becomes partially set and adhesive, next applying a layer of tarred-felt paper to the asphaltum layer under sufficient pressure to effect an adhesive union therewith, and finally applying to the surface of the tarred-felt paper a second layer of hot asphaltum and permitting the same to set.

2. That method of producing an underground receptacle which consists first in applying a layer of hot asphaltum to the surface of a tank, and permitting said layer to partially set, next applying a layer of tarred-felt paper to the layer of asphaltum, next wrapping the tarred-felt paper with a binding-strand, and finally applying a second layer of asphaltum to the surface of the paper.

3. That method of producing an underground receptacle which consists first in applying a layer of hot asphaltum to a tank, and permitting said layer to become partially set, next applying a layer of tarred-felt paper to the asphaltum layer, next binding the tarred-felt paper with a flexible binding-strand, next applying a second layer of asphaltum to the surface of the bound paper, next applying a layer of fabric upon the asphaltum layer while the latter is in an adhesive condition, and next applying to the fabric a final layer of asphaltum.

4. That method of producing an underground receptacle which consists in applying alternate layers of asphaltum and tarred-felt paper to a tank, binding the tarred-felt paper layer or layers with a flexible binding strand or strands, applying a layer of fabric to the last layer of asphaltum, and finally applying an asphaltum layer to the outer surface of the fabric.

5. An underground receptacle of the character specified, comprising a tank equipped with a protective covering of asphaltum and tarred-felt paper, said paper being bound with a flexible binding-strand.

6. An underground receptacle of the character specified, comprising a tank equipped with a protective covering composed of alternate layers of asphaltum and tarred-felt paper, a flexible binding-strand wound upon the layer or layers of tarred-felt paper, a fabric layer imposed upon the outer layer of asphaltum, and a final layer of asphaltum covering the fabric.

7. That method of producing an underground receptacle which consists in applying alternate layers of asphaltum and tarred-felt paper to a tank, next applying a layer of fabric to the last layer of asphaltum, and finally applying an asphaltum layer to the outer surface of the fabric.

8. An underground receptacle of the character specified, comprising

a tank equipped with a protective covering composed of alternate layers of asphaltum and tarred-felt paper, a fabric layer imposed upon the outer layer of asphaltum, and a final layer of asphaltum covering the fabric.

697,955. SOLDERLESS JOINT MEAN FOR THE CANS OR OTHER METALLIC VESSELS. WALTER THOMPSON, Toronto, Canada, assignor, by mesne assignments, to the Pasteur's Sanitary Can Company, Paterson, N. J., a Corporation of New Jersey. Filed Oct. 12, 1901. Serial No. 73,708. (No model.)

Claim.—1. A lock-joint for sheet-metal vessels having the portions of its metal at spaced intervals throughout the length and width of said joint indented and stretched, and then displaced, transversely of said joint, to form transverse ribs.

2. A lock-joint for sheet-metal vessels provided with elongated transverse indentations arranged at right angles to the joint, each of said elongated indentations being curved inwardly.

3. A sheet-metal vessel having the meeting edges of its body portion interlocked with each other to form the side seam or joint, said seam or joint being provided with transverse elongated indentations and being curved or channelled inwardly to a longitudinal direction, said indentations being arranged at right angles to the joint substantially as described.

4. A sheet-metal vessel having the meeting edges of its body portion interlocked with each other to form the side seam or joint, said seam or joint being provided with a series of transverse elongated indentations increasing in length toward the center of the joint and extending into the body portion of the sheet-metal vessel, substantially as described.

697,956. SOLDERLESS JOINT MEAN FOR SHEET-METAL VESSELS. WALTER THOMPSON, Toronto, Canada, assignor, by mesne assignments, to the Pasteur's Sanitary Can Company, Paterson, N. J., a Corporation of New Jersey. Filed Nov. 20, 1901. Serial No. 80,700. (No model.)

Claim.—1. A solderless lock-joint for sheet-metal vessels provided with a series of conical indentations arranged longitudinally of the joint, any two adjoining indentations being spaced a distance approximating their width to thus form alternating ridges and effect an unbroken contact between the surfaces of the layers of the joint throughout the length of said series to form a continuous undulating seam, substantially as described.

2. A lock-joint for sheet-metal vessels provided with conical-shaped indentations arranged in close proximity to each other and forming curved ridges, the layers of the joint being thickest at the top of the ridges and thinnest at the point of the conical-shaped indentations, substantially as described.

3. A solderless lock-joint for sheet-metal vessels provided with a series of conical indentations arranged longitudinally of the joint, any two adjoining indentations being spaced a distance approximating their width to thus form intermediate ridges and effect an unbroken contact between the surfaces of the layers of the joint throughout the length of said series to form a continuous undulating seam, and said series of indentations being arranged in parallel rows, substantially as described.

697,957. METHOD OF EXTRACTING RUBBER-LIKE GUM FROM GREENWOOD. ALBERT T. WHITTEN and FRANK R. BLAIR, Green City, Mo., assignors, by direct and mesne assignments, of one-third to William H. Stewart and Charles J. Kappeler, Green City, Mo. Filed Sept. 20, 1901. Serial No. 74,008. (No specimens.)

Claim.—1. The method of extracting a rubber-like gum from the greenwood-plant, which consists in crushing the shells of said plant, steeping the same in water, withdrawing the water and subjecting the material to steam, expressing the liquid, partially evaporating the liquid withdrawn, and dissolving the gum therefrom by a rubber solvent, substantially as described.

2. The method of extracting a rubber-like gum from the greenwood-plant, which consists in crushing the shells of said plant, steeping the crushed material in water and withdrawing the liquid from the shells, evaporating the bulk of the water and replacing the same by a solvent of rubber, and distilling the solvent and its contained material to produce a gum similar in every respect to caoutchouc.

697,959. TOY. JOHN FLEMING, Chicago, Ill. Filed Sept. 12, 1901. Serial No. 73,147. (No model.)

Claim.—1. A toy comprising a shallow box provided with sockets extended in a row around at the margin of its cover, steps adapted to slide and open the sockets and two groups of transversely-arranged levers mounted within the box and connected with the steps, the arrangement of the levers and steps relatively to the row of sockets being as specified.

2. A toy comprising a shallow box provided with registering holes in its top and bottom extended in a row around at the margin, steps adapted to work in said holes, and two groups of transversely-arranged and individually-operative levers mounted on filars located in different places within the box, each group of levers being connected with a portion of the steps arranged at opposite ends of the group as specified.

3. A toy comprising a shallow box provided with sockets extended in a row at the margin of its cover, steps adapted to slide and open the sockets, two groups of transversely-arranged levers mounted within the box and connected with the steps, the arrangement of the levers and steps relatively to the row of sockets being as shown, and means for limiting the movement so as to prevent the projection of the steps above the upper surface of the cover as specified.

DESIGNS.

85,858. WRITING-PEN-HOLDER. JAMES A. WOOLLEY, Brooklyn, Tex. Filed Mar. 14, 1902. Serial No. 68,570. Term of patent 7 years.

Claim.—The design for a handle of a spoon, fork or similar article, as herein shown and described.

85,859. HANDLE FOR SPOON, FORK OR SIMILAR ARTICLE. WILLIAM G. CORRIAN, Providence, R. I., assignor to Corrian Manufacturing Company, Providence, R. I. Filed Mar. 24, 1902. Serial No. 68,816. Term of patent 7 years.

Claim.—The design for the handle of a spoon, fork or similar article, as herein shown and described.

85,860. HANDLE FOR SPOON, FORK OR SIMILAR ARTICLE. ROBERT MAYNARD, Taunton, Mass., assignor to Reed & Barton Corporation, Taunton, Mass., a Corporation of Massachusetts. Filed Mar. 21, 1902. Serial No. 68,826. Term of patent 14 years.

Claim.—The design for a handle for spoon, fork or similar article, substantially as shown and described.

85,861. HANDLE FOR SPOON, FORK OR SIMILAR ARTICLE. ROBERT MAYNARD, Taunton, Mass., assignor to Reed & Barton Corporation, Taunton, Mass., a Corporation of Massachusetts. Filed Mar. 21, 1902. Serial No. 68,826. Term of patent 14 years.

Claim.—The design for a handle for spoon, fork or similar article, substantially as shown and described.

85,862. HANDLE FOR SPOONS OR SIMILAR ARTICLES. ROBERT H. H. BURR, Bridgeport, Conn. Filed Mar. 5, 1902. Serial No. 84,972. Term of patent 7 years.

Claim.—The design for a handle for a spoon or similar article, substantially as described and shown.

85,863. VEGETABLE-DISH. ROBERT LEVIN JENNISON, Hanley, England. Filed Feb. 12, 1902. Serial No. 85,008. Term of patent 24 years.

Claim.—The design for a vegetable-dish, substantially as herein shown and described.

85,864. TOY BANK. JOHN W. BULLMAN, Mount Joy, Pa. Filed Mar. 26, 1902. Serial No. 85,816. Term of patent 7 years.

Claim.—The design for a toy bank, as herein shown and described.

85,865. CIGARETTE-BOX. GEORGE F. BULLER, New York, N. Y. Filed Mar. 1, 1902. Serial No. 77,416. Term of patent 14 years.

Claim.—The design for a cigarette-box as herein shown and described.

85,866. OIL-STOVE. WILLIAM E. JEAVER, Cleveland, Ohio. Filed Dec. 20, 1901. Serial No. 87,044. Term of patent 7 years.

Claim.—The design for an oil-stove, substantially as shown and described.

85,867. COOKING STOVE OR RANGE. JOHN J. JEAVER, Buffalo, N. Y., assignor to Jervis & Company, Buffalo, N. Y., a Corporation of New York. Filed Feb. 12, 1902. Serial No. 84,908. Term of patent 7 years.

Claim.—The design for a range or cooking-stove, substantially as shown and described.

85,868. CART-BODY. JAMES G. HENNINGSON, Philadelphia, Pa. Filed Oct. 14, 1901. Serial No. 73,994. Term of patent 7 years.

Claim.—The design for a cart-body, as herein shown and described.

85,869. CONNECTING-Piece FOR BEDSTEAD. JAMES H. DUFFY, Buffalo, N. Y. Filed Feb. 17, 1902. Serial No. 94,968. Term of patent 24 years.

Claim.—The design for a connecting-piece for bedsteads substantially as shown and described.

85,870. SEWING-MACHINE CABINET. WILLIAM FENNER, Rockford, Ill., assignor to East Rockford Mould Company, Rockford, Ill. Filed Mar. 20, 1902. Serial No. 99,314. Term of patent 24 years.

85,870.

Claim.—The design for a sewing-machine cabinet, substantially as herein shown and described.

85,871. PIANO-PLAYER CASE. HENRIET E. SHARP, Bridgeport, Conn. Filed Mar. 20, 1902. Serial No. 99,314. Term of patent 7 years.

Claim.—The design for a piano-player case, as herein shown and described.

85,872. CASES FOR VENDING-MACHINES. WILLIAM C. HENDON, Detroit, Mich., assignor to Ellsworth & Bryant, Detroit, Mich. Filed Feb. 1, 1902. Serial No. 62,503. Term of patent 7 years.

Claim.—The design for a casing for vending-machines, substantially as herein shown and described.

85,873. BORN-SUPPORTING ARM FOR TALKING-MACHINES. LOUIS P. VALERIE, New York, N. Y. Filed Mar. 19, 1902. Serial No. 62,504. Term of patent 7 years.

Claim.—The design for a born-supporting arm for talking-machines, as herein shown and described.

85,874. CASE FOR TALKING-MACHINES. LOUIS P. VALERIE, New York, N. Y. Filed Mar. 19, 1902. Serial No. 62,505. Term of patent 7 years.

Claim.—The design for a case for talking-machines, as herein shown and described.

85,875. SHOE-LACING. HENRY W. BLAIR, New York, N. Y. Filed Feb. 24, 1902. Serial No. 62,506. Term of patent 7 years.

Claim.—The design for a shoe-lacing, substantially as herein shown and described.

85,876. CASKET-TRIMMING. WILLIAM E. STEVEN, New Haven, Conn., assignor to Stegert & Company, New Haven, Conn., a Corporation of Connecticut. Filed Dec. 15, 1901. Serial No. 62,507. Term of patent 14 years.

Claim.—The design for a casket-trimming, as herein shown and described.

TRADE-MARKS

REGISTERED APRIL 13, 1902.

88,095. DOLLA. HANCOCK & Co., New York, N. Y. Filed Jan. 25, 1901.

MARGUERITE

Essential feature.—The word "MARGUERITE." Used since November 18, 1901.

88,096. SPOONS. J. B. & E. M. KNOWLES Co., Providence, R. I. Filed Jan. 2, 1901.

RED CROSS

Essential feature.—The words "RED CROSS." Used since July 1, 1901.

88,097. COVER AND LAD WRITING-PAPER. FURNICULAR PAPER Co., Ypsilanti, Mich. Filed Nov. 17, 1900.

Essential feature.—The representation of a shield surmounted by a crown and a monogram of the letters "F P C" in the center of the shield. Used since March 1, 1901.

88,098. BRASS-SILVER. LORRY SILVER Co., New York, N. Y. Filed Mar. 6, 1901.

LIBERTY

Essential feature.—The word "LIBERTY" in connection with a head bearing a torch. Used since February 6, 1901.

88,099. WRITING-UTENSILS. ALFRED HENNINGSEN AND COMPANY, New York, N. Y. Filed Sept. 11, 1900.

88,099.

Essential feature.—A rectangular frame having the representation of a bell ornamented by a band of shamrocks held fast therein, and the words "BELL FAST" in connection therewith. Used since August 25, 1901.

88,100. CERTAIN HANDED FABRICS. GEORGE WALKER, New York, N. Y. Filed Jan. 24, 1901.

ROUGH RIDER

Essential feature.—The representation of a mounted cowboy in the uniform of the rough-rider regiment of the late Spanish-American war and the words "ROUGH RIDER." Used since January 1, 1902.

April 15, 1902

U. S. PATENT OFFICE.

657

88,101. CERTAIN HANDED DRY GOODS. FRANK CHAMBER, New York, N. Y. Filed Mar. 15, 1901.

Essential feature.—The representation of a crown, a shield displaying a gallery and fleur-de-lis, and a palm branch. Used since July 1, 1900.

88,102. CERTAIN HANDED DRY GOODS. JAMES HANCOCK, New York, N. Y. Filed Jan. 27, 1901.

Essential feature.—The representation of a griffin having a dragon-like body and tail and the wings, legs, feet, and back of a lion, the feet of the griffin appearing as grasping a palm-leaf branch and the said representation appearing on a background inclosed by an ornamental circle or border. Used since 1900.

88,108. SHIRTING AND DRILL. WILLIAM BROWN, New York, N. Y. Filed Feb. 21, 1901.

Essential feature.—The representation of the head and neck of a Chinese dragon surrounded by a vast quantity of hair, which forms a thick mass, with two short curved horns extending upward from the top of the head and a long tail or antenna depending from each side. Used since November 25, 1901.

88,104. SHIRTING AND DRILLING. THE LORRY SILVER Co., New York, N. Y. Filed Mar. 4, 1901.

Essential feature.—The representation of an opium with its young. Used since January, 1901.

88,105. SHIRTING AND DRILLING. THE LORRY SILVER Co., New York, N. Y. Filed Mar. 4, 1901.

Essential feature.—The representation of a dog leading a horse. Used since January, 1901.

88,106. SHIRTING, SHIRTING, AND DRILL. EDWARD L. BROWN, New York, N. Y. Filed Feb. 7, 1901.

Essential feature.—The representation of a figure holding a staff or pole. Used since September, 1900.

88,107. **CORDUROY BROWN-KINDEN** Mrs. J. CORDUROY & Co.,
San Francisco, Cal. Filed Mar. 6, 1902.

Essential feature.—The word "THE IDEAL." Used since 1892.

88,108. **READY-MADE CLOTHING FOR MEN AND BOYS** THE
COLUMBIAN, JOHN P. FINE CO., Cleveland, Ohio. Filed Mar. 14, 1902.

Essential feature.—The representation of a shield upon which ap-
pears the word "CLOTHES" and the representation of a lion, said
shield being surrounded by suitably ornamented scrolls or scrolls. Used
since October 15, 1901.

88,109. **LADIES, MEN, AND CHILDREN'S BOOTS AND SHOES**
G. P. FINE & Co., Rochester, N. Y. Filed Mar. 16, 1902.

Essential feature.—The words "LIBERTY BELLS." Used since
February 6, 1902.

88,110. **SHOES AND BOOTS** CHAMBERLAIN SHOE MFG. CO., Cham-
berburg, Pa. Filed Mar. 15, 1902.

ECLECTIC

Essential feature.—The word "ECLECTIC." Used since Feb-
ruary 1, 1902.

88,111. **CERTAIN NAMED CROCHERS** Mrs. E. HOGAN & Co.,
Baltimore, Md. Filed Feb. 4, 1902.

Essential feature.—The word "ORIOLE" and the pictorial repre-
sentation of the bird of that name upon a leafy branch. Used since May
10, 1900.

88,112. **CONDENSED MILK** HENRIETTA MILK CONDENSED CO.
Highland, N. Y. Filed Aug. 4, 1901.

SUCCESS

Essential feature.—The word "SUCCESS." Used since August
9, 1900.

88,113. **CERTAIN NAMED DAIRY PRODUCTS** ADAMS DAIRY CO.
New York, N. Y. Filed July 25, 1901.

TIP TOP

Essential feature.—The words "TIP TOP." Used since January,
1902.

88,114. **CORSET** HENRIETTA FASHION & Co., New York,
N. Y. Filed Feb. 1, 1902.

Essential feature.—The conventional representation of the sun bear-
ing human features, the rays being lanceolate, and the whole enclosed in
a rectangular frame filled in with wavy lines. Used since November,
1876.

88,115. **FRUIT AND HONEY** WHELAN & HARRIS, Boston, Mass.
Filed Mar. 18, 1902.

Essential feature.—The representation of a heart and the letters
"W" and "H." Used since February 21, 1902.

88,116. **CECIL** JOHN BUCHANAN AND COMPANY, Louisville, Ky.
Filed Mar. 12, 1902.

SENOJ

Essential feature.—The word "SENOJ." Used since April, 1900.

88,117. **MEDICAL WATER** THE AMERICAN DRUG CO., Atlanta,
Ga. Filed Feb. 24, 1902.

ABILENA

Essential feature.—The word "ABILENA." Used since April 25
1901.

88,118. **SPRING-WATER** GEORGE J. GARDNER, Lowell, Mass. Filed
Feb. 17, 1902.

EI-AZHAR

Essential feature.—The compound word "EI-AZHAR." Used
since July, 1900.

88,119. **CHARITABLE** BUCHANAN & COMPANY, New York, N. Y.
Filed Feb. 27, 1902.

ANGLO-EGYPTIAN

Essential feature.—The compound word "ANGLO-EGYPTIAN."
Used since October, 1901.

88,120. **CHERRY-CURE** THE NEW YORK VINEGAR MANUFACTUR-
ING CO., New York, N. Y. Filed Feb. 15, 1902.

YA-MA

Essential feature.—The compound word "YA-MA." Used since
January 1, 1902.

88,121. **WASHING COMPOUND** FINEST GENERAL CO., New
York, N. Y. Filed Mar. 10, 1902.

NEXT-TO

Essential feature.—The compound word "NEXT-TO." Used
since February 24, 1902.

88,122. **TRIPLE SOAP, LAUNDRY SOAP, DRY SOAP, SOAP-POW-
DER, AND DETERGENTS** LEVIN BROTHERS, London, Port Sunlight,
England. Filed Mar. 12, 1902.

PLANTOL

Essential feature.—The word "PLANTOL." Used since August
21, 1901.

88,123. **PERFUME** WHELAN & HARRIS, St. Louis, Mo.
Filed Mar. 14, 1902.

FLORESSENCE

Essential feature.—The word "FLORESSENCE." Used since
February 21, 1902.

88,124. **DEPILATORY** HENRI WHELAN & HARRIS, London, England.
Filed Feb. 12, 1902.

DRASETA

QUEEN OF HAIR REMEDIES

Essential feature.—The words "DRASETA" and "QUEEN OF
HAIR REMEDIES" and the representation of a queen's crown. Used
since January 8, 1902.

88,125. **MEDICAL TABLETS FOR RESPIRATION, COUGH, AND
ALLIED AFFECTIONS** RICHARD G. HARRIS, Milwaukee, Wis. Filed Oct.
21, 1901.

R

Essential feature.—The letter "R." Used since October 10, 1901.

88,126. **RESCUES IN CAPSULE FORM FOR THE TREATMENT OF
VARIETIES OF DYSPEPSIA** RICHARD G. HARRIS, Columbus, Ohio.
Filed Feb. 14, 1902.

88,126.

Essential feature.—The representation of an Indian walking through a forest, with his left hand extended, of a woman standing on a porch of a dwelling, with her right hand extended in the act of releasing a bird, a curved banner extending across the upper central portion of the trade-mark, on which is inscribed: "OUT OF DARKNESS AND INTO THE LIGHT," and a scroll occupying the central and lower portion of the trade-mark, on which is inscribed: "THESE ARE MADE FROM THE ROOTS THAT GROW IN THE TURF, SO CARRY THIS MESSAGE ALL OVER THE EARTH: OUT FROM THE SHADOWS AND ACROSS THE SEA! THAT ALL MAY KNOW WHAT THEY HAVE DONE FOR ME." Used since March 1, 1892.

88,127. REMEDIES FOR CURING BRUISES, CALLUSES, AND WARTS. JOHN JAY LITTLE, Milwaukee, Wis. Filed Feb. 3, 1902.

Essential feature.—The word "OMEGA," the representation of the Greek letter "omega," and the human foot. Used since January 10, 1901.

88,128. REMEDIES FOR DISEASES OF THE LUNGS AND THROAT. O'ROURKE AND HOWLEY, Little Falls, N. Y. Filed Mar. 15, 1902.

SAR-NAC

Essential feature.—The compound word "SAR-NAC." Used since February 1, 1902.

88,129. ALTERNATIVE COMPOUND. ALLEN H. SCHULZ, New York, N. Y. Filed Mar. 11, 1902.

MODOMERCURO

Essential feature.—The word "MODOMERCURO." Used since October 10, 1901.

88,130. VARNISHES. FRANK HAPPEL, Cincinnati, Ohio. Filed Feb. 18, 1902.

Jet-E-Nam

Essential feature.—The compound word "JET-E-NAM." Used since October, 1899.

88,131. LIQUID GUM-RESIN. HENRY CHANDLER AND HANCOCK-TURNER COMPANY, Kansas City, Mo. Filed Mar. 20, 1902.

Nic-Sul

Essential feature.—The compound word "NIC-SUL." Used since January 1, 1902.

88,132. PAINT AND WHITE LEAD. HANNAH BROTHERS WHITE LEAD COMPANY, East St. Louis, Ill. Filed Feb. 19, 1902.

Essential feature.—An annular red stripe produced in or applied to a keg or pail containing paint or white lead. Used since April 1, 1901.

88,133. ROOF-PAINTS OR PAINTS FOR METAL AND COMPOSITION ROOFING. DAYTON FIRE ROOFING CO., Dayton, Ohio. Filed Mar. 14, 1902.

EGYPTIA

Essential feature.—The word "EGYPTIA." Used since January, 1897.

88,134. ASPHALTUM. GEORGE ANGELO CO., Philadelphia, Pa., and Los Angeles, Cal. Filed Mar. 12, 1902.

OBISPO

Essential feature.—The word "OBISPO." Used since August 17, 1900.

88,135. CEMENT. LUTHER FURNACE CEMENT CO., East Orange, N. J. Filed Apr. 20, 1902.

Essential feature.—The word "OBISPO" and the representation of an Indian known as "Opowaw." Used since March 1, 1901.

88,136. EXPLOSION. SAFETY RETORTS COMPANY, New York, N. Y. Filed Feb. 1, 1902.

Essential feature.—The word "MASURITE" enclosed in a diamond, which diamond is itself enclosed in three larger diamonds. Used since February 1, 1902.

88,137. CERTAIN KINDS EXPLOSION, POWER, AND ELECTRIC BATTERIES. LAFAYETTE POWER COMPANY, New York, N. Y. Filed Nov. 14, 1901.

88,137

Essential feature.—The representation of a wreath and the representation of a flag on the field enclosed by the wreath. Used since January 1, 1902.

88,138. FIRE-EXTINGUISHING COMPOUND AND FIRE-EXTINGUISHING IN POWDER FORM. CONSUMERS A. BARNES, Bay City, Mich. Filed Mar. 4, 1902.

AJAX

Essential feature.—The word "AJAX." Used since February 12, 1902.

88,139. CARPET-CLEANING IMPLEMENTS AND APPLIANCES. BARNES HARDWARE COMPANY, St. Louis, Mo. Filed Feb. 12, 1902.

KARPET KING

Essential feature.—The words "KARPET KING." Used since March, 1902.

88,140. MALS FOR ONE-OPERATED MACHINES. EDWARD T. BERNARD, Richmond, Va. Filed Mar. 20, 1901.

I-DO
—
U-DO

Essential feature.—The compound word "I-DO-U-DO." Used since March 1, 1902.

88,141. SEWING-MACHINES AND ATTACHMENTS. WILLIAM ALLEN CHURCH, New York, N. Y. Filed Dec. 20, 1902.

IONA

Essential feature.—The word "IONA." Used since September 12, 1902.

88,142. CHAIN-BLOCK. THE YALE & TOWNE MFG. CO., Stamford and Braintree, Conn.; New York, N. Y.; Boston, Mass.; Philadelphia, Pa.; Chicago, Ill. and San Francisco, Cal. Filed Mar. 6, 1902.

DUPLEX

Essential feature.—The word "DUPLEX." Used since January, 1897.

88,143. VENEER-BLOCK. FRANKLIN F. WHEAT, New York, N. Y. Filed Jan. 1, 1902.

BARWEST

Essential feature.—The word "BARWEST." Used since July 1, 1901.

LABELS

REGISTERED APRIL 18, 1902.

9,079.—Title: "ANTISEPTIC HEALTH FABRIC." (For Fabric.) JOHN S. GIVENS, New York, N. Y. Filed March 25, 1902.

9,080.—Title: "EL PAGADO." (For Cigars.) A. C. HANCOCK & CO., Chicago, Ill. Filed March 24, 1902.

9,081.—Title: "LA FLOR DE LUM MARTINEZ." (For Cigars.) THE MARTINEZ & HANCOCK CO., New York, N. Y. Filed March 24, 1902.

9,082.—Title: "NONE SUCH FURNITURE & FLOOR POLISH." (For Furniture and Floor Polish.) GEORGE W. SARGENT, Philadelphia, N. J. Filed November 25, 1901.

9,083.—Title: "SNYDER'S ALL FOOD EMULSION." (For a Medicine.) MARGARET ELIZABETH SNYDER, Brooklyn, N. Y. Filed February 25, 1902.

9,084.—Title: "SWORDS GREAT TONIC AND SYSTEM RENOVATOR." (For a Medicine.) SWORDS MEDICINE CO., Philadelphia, Penn. Filed March 24, 1902.

PRINTS

REGISTERED APRIL 18, 1902.

489.—Title: "SPRING CLOTHING AND APPAREL." (For Clothing.) W. G. BORN, Chicago, Ill. Filed March 26, 1902.

490.—Title: "DREXEL BOX." (For Overcoats.) KUN, NATHAN & FISCHER CO., Chicago, Ill. Filed March 24, 1902.

491.—Title: "THE HANSFIELD." (For Overcoats.) KUN, NATHAN & FISCHER CO., Chicago, Ill. Filed March 24, 1902.

492.—Title: "THE HARVARD SACK." (For Sack-Covers.) KUN, NATHAN & FISCHER CO., Chicago, Ill. Filed March 24, 1902.

493.—Title: "THE KENMORE SACK." (For Sack-Covers.) KUN, NATHAN & FISCHER CO., Chicago, Ill. Filed March 24, 1902.

494.—Title: "KEDMAN'S ABSORPTION FOOD SACHET." (For an Absorption Food-Sachet.) KEDMAN & CO., Philadelphia, Pa. Filed March 19, 1902.

DECISIONS
OF THE
COMMISSIONER OF PATENTS
AND OF
UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

SWIHART v. MAULDIN.

Decided November 25, 1897.

1. INTERFERENCE—REDUCTION TO PRACTICE—DECISION COMPLETE,
BUT UNSATISFACTORY.

Where twelve complete scales embodying every feature of the interference issue were made and shipped to customers for test in practical use and they were all returned as unsatisfactory, *Held* not a reduction to practice of the invention.

2. SAME—SAME—CONSTRUCTION OF DEVICE NOT SUFFICIENT UN-
LESS SATISFACTORY.

The mere construction of a device embodying the elements of the issue cannot be accepted as a reduction to practice unless that device proves to satisfactory in use as to demonstrate the practicability of the invention.

3. SAME—SAME—DEFECTS CORRED BY MECHANICAL SKILL.

The fact that an unsuccessful device could have been made successful by mere mechanical skill does not make that device constitute a reduction to practice, since until made operative it does not demonstrate the practicability of the invention any more than would drawings or a model.

4. SAME—SAME—MACHINE AS A WHOLE NOT SUCCESSFUL.

Where the mechanism of the claim operates successfully, it is not necessary that all parts of the machine in which it is used shall be mechanically perfect; but where the mechanism claimed is the part which proves defective *Held* not a reduction to practice.

APPEAL FROM EXAMINERS-IN-CHIEF.

SPRING-BALANCE SCALES.

Application of John H. Swihart filed November 1, 1897, No. 657,126. Application of James L. Mauldin filed May 3, 1897, No. 634,864.

Messrs. Thurston & Bates and Mr. H. H. Bliss for Swihart.

Mr. Ira C. Kochne and Messrs. Church & Church for Mauldin.

ALLEN, Commissioner:

This is an appeal by Swihart from the decision of the Examiners-in-Chief affirming the decision of the Examiner of Interferences awarding priority of invention to Mauldin upon the following issue:

1. In a spring-balance scale, the combination of a spring-suspended runner having, on its lower end, means for suspending the load, with a fixed dash-pot cylinder, its plunger, and a plunger-rod which is flexibly connected at one end with the runner and at the other end with the plunger.

2. In a spring-balance scale, the combination of a cylindrical scale-rod having a hook at its lower end, and a spring-suspended runner which extends out through said hole and has on its lower end means for suspending the load, with a pneumatic cylinder closed at one end and open at the other, and having at its closed end and external wings which are secured to the cylindrical scale-rod, a plunger movable in said cylinder, and a plunger-rod which is flexibly connected at one end with the plunger and at the other end with the runner.

9900—3—11

It seems that the novelty in this issue resides in the dash-pot provided with the flexibly-connected plunger-rod, the purpose and effect of these elements being to prevent shock and to bring the scale to rest quickly. In allowing the claim upon an *ex parte* appeal the Examiners-in-Chief held that there was no invention, broadly, in using a dash-pot in a scale of this kind for the purpose in view, but that the use of flexible connections for the plunger-rod overcame the practical difficulty met in applying a dash-pot to that use and rendered the claim patentably novel. Dash-pots of various kinds are concededly old for analogous purposes.

Swihart, although the later by six months to file his application, claims the earlier date of conception and reduction to practice. He alleges in his statement conception in November, 1896, and reduction to practice the latter part of December 1896. It is not contended, however, that the evidence in his behalf proves reduction to practice earlier than February, 1897. It is claimed that a dozen machines embodying the invention were then completed, shipped to customers, and put in use. No other machines embodying the invention seem to have been made until July or August, 1897. His application was filed November 1, 1897.

Mauldin claims to have conceived the invention early in 1897 and to have reduced it to practice in March or April of that year. His application was filed May 3, 1897. May 3 is the earliest date which can be accorded him for a reduction to practice, although there seems to be no doubt that about or shortly after that time he built a successful machine embodying the invention.

It is clear that if Swihart did build his machines in February, 1897, as alleged, and they constituted a reduction to practice of the invention he must prevail, since that was prior to Mauldin's alleged date of conception.

The Examiners-in-Chief were of the opinion from the evidence that Swihart made the machines, as alleged, in February; but the majority concluded that they were unsatisfactory and constituted nothing more than abandoned experiments. They further decided that Swihart was not thereafter exercising diligence when Mauldin entered the field and that therefore, although the first to conceive, he could not be regarded as the first inventor, since he was the last to reduce to practice.

993

The evidence that the machines were actually built in February, 1897, is far from satisfactory and convincing; but even admitting that the facts are precisely as contended by Swihart it is believed that the majority of the Examiners-in-Chief were right in their conclusion that the machines amounted to nothing more than abandoned experiments. The scales are said to have been shipped to customers for the purpose of testing their practicability by actual use, (Hoyt, Q. 52,) and it is admitted that they were every one returned as unsatisfactory. According to the testimony they embodied every feature of the counts of this interference; but it is well settled that the mere construction of a device embodying the elements of the issue cannot be accepted as a reduction to practice unless that device proves so satisfactory in use as to demonstrate the practicability of the invention. This is the purpose of the legal requirement for a reduction to practice. When the scales were returned, Swihart did not question the fact that they would not work satisfactorily, but dismantled them, and when he had discovered a different kind of plunger for his dash-pot reconstructed them with this new plunger and again sent them out for use.

The reason alleged for the failure of the first scales to work properly is that there was too much friction between the plunger and tube of the dash-pot. The plungers of those scales were made of hard rubber, and after they were returned Swihart learned indirectly from one Leganke that graphite could be used in making the plungers and would operate with less friction. He thereupon introduced this feature into his scales and found that they were then satisfactory; but this was after Mauldin had obtained the same information from Leganke and had successfully reduced the invention to practice.

The issue in this case includes the plunger, but contains no limitation as to the material of which it is made, and for this reason the dissenting member of the board of Examiners-in-Chief regards the use of the rubber plunger as a reduction to practice. Graphite plungers were old prior to Swihart's invention, although he did not know of them, and it is therefore argued that the fact that the rubber plungers were not satisfactory is not fatal to his claim to a reduction to practice, since any one skilled in the art could have cured the defect by the substitution of the well-known graphite for the rubber. It is said that the device was not inoperative and could have been rendered satisfactory in operation by mere mechanical skill. It seems probable, however, that the device was in fact inoperative as thus construed, in that it would not weigh correctly, and there is certainly no proof that it would weigh correctly. The evidence all indicates that it would not.

It was not demonstrated that a plunger and flexible connections as a part of a dash-pot used in scales would operate practically and prove satisfactory until a device which proved satisfactory had actually been made. The argument that a mechanic skilled in the art could have constructed

a practical device without the exercise of invention after seeing Swihart's first machines is not pertinent, since it could be made with equal force in regard to a mere model, or even drawings. It is well settled that a model or drawings, however complete, cannot be accepted as a reduction to practice, although any mechanic could from them make a successful machine. (*McCormick v. Cleal*, 88 O. G., 1514; *Hunter v. Stikeman*, 85 O. G., 610.) This is true also of an unsuccessful machine. (*Glidden v. Noble*, 71 O. G., 411.)

The unsuccessful machines in the present case did not demonstrate the fact that the invention would be a practical success any more than drawings or a model would have demonstrated that fact. We know now that a successful machine can be made and how it must be done; but Swihart did not know it when those machines were returned.

A case of this kind is to be distinguished from such a case as was considered by the court in *National Cash Register Co. v. Lamson Co.*, (67 O. G., 680; C. D., 1894, 283.) In that case the mechanism of the claim was made and operated successfully, and the court held that it was not of consequence that other parts of the machine not involved in the claim were not mechanically perfect and that the machine as a whole did not operate successfully. In the present case it was the combination of the issue which proved unsatisfactory and not some other part of the machine. The other parts of the machine were the same as in previous devices. A plunger and flexible plunger-rod are essential features of the present issue, and until they proved satisfactory the invention was not complete.

After the alleged shipment of the defective machines in February Swihart seems to have done nothing in regard to the invention for some months and until after Mauldin had entered the field, reduced the invention to practice, and filed his application. The evidence does not show that he was exercising diligence when Mauldin made this invention.

As above stated, the evidence that machines embodying this invention were made and sold as early as February, 1897, is not satisfactory. It consists of oral testimony alone, given between three and four years after the event and in answer to leading questions. Several witnesses testify positively to the fact; but there are contradictions in their testimony which show them to have been mistaken as to material dates and facts in regard to this invention and which therefore make their testimony somewhat unreliable. There are also surrounding circumstances which throw still further doubt upon the matter.

The first form of dash-pot said to have been used by Swihart was a drawn-brass tube with a chamois-skin plunger provided with a rigid stem. The second was substantially the same with a flexible stem. The third was the one said to have been embodied in the twelve scales sold in February, and it consisted of a cast-brass cylinder reamed out perfectly smooth and a plunger made of hard rubber and having a flexible stem. It is said to be impos-

[Vol. 99, No. 3.]

sible to make a drawn-brass cylinder sufficiently smooth to be used with a hard-rubber plunger. It is material, therefore, to know when Swihart or the National Computing Scale Company, at whose works the scales were made, first made cast-brass cylinders. Evidence on behalf of Mauldin makes it seem probable that it was after Mauldin had made the invention. It is necessary that such cylinders be reamed out, and the evidence shows that the company obtained a reamer the latter part of April, 1897, and there is no evidence that it had a reamer before that time. Hoyt says (Q. 8, p. 151) that there was nothing else at the factory upon which this reamer could be used except the dash-pots. It was not satisfactory, however, since it was too short to properly ream cylinders of the length required, and Swihart's Exhibit Cast Dash-Pot, which is said to be one of the first made and used on the scales, was not reamed by it. This is admitted and is apparent, since it is not of the same size. It is stipulated that a reamer which could have been used to make this exhibit was obtained by the company in June or July, 1897. The testimony of the witness Neuman is to the effect that he used this reamer in making the cylinders, and Swihart admits that Neuman is the man who had charge of making the cylinders. Neuman says that he made them after a visit to Leganke's shop, where he obtained information about the graphite plungers, and this was admittedly after Mauldin had made the invention. Hoyt says (X-Qs. 17 and 18, p. 153) that it is possible that the company may have had other reamers with which the cylinders were made; but there is no proof that they did have them, and this is the only explanation of the alleged making of the cylinders before the proved date on which reamers were obtained. The evidence on this question adduced by Mauldin placed the burden on Swihart of showing clearly that he did have the tools with which to make the cylinders; but he has produced no such proof. It is natural to suppose that after the lapse of time in this case the witnesses may have become confused on the question whether they saw cast cylinders or drawn cylinders when they are relying solely upon memory, and therefore surrounding circumstances of this kind have much weight.

The witness Elliot claims to have seen a dash-pot in Swihart's experimental room while he was working for the company, and he left in February, 1897. He does not know the construction of the plunger, however, or its connection with the stem and never saw the device in use in a scale. He says that the plunger was in the cylinder and that the stem was at an angle to the line of the cylinder, thus intimating that there was a flexible connection between the stem and plunger. This is not satisfactory proof of the fact, however, since the position of the stem may have been due to some other cause.

Several witnesses produced by Mauldin state that they were employed by the National Computing Scale Company at the time the scales are said to have been made and that they did not see a dash-pot

[Vol. 99,

scales until June or July. This testimony is negative, and therefore not conclusive, but is entitled to some consideration in view of the unsatisfactory character of the positive testimony.

It appears that in May, 1897, Mauldin brought his scale to Hoyt, the president of the National Computing Scale Company, and showed it to him for the purpose of having him to take up the invention. Hoyt refused to do so and claims to have had Swihart show Mauldin the dash-pot scale which he had made as proof that the company already had a similar scale. The scale shown Mauldin then, however, is admittedly one not having the flexible connection for the plunger, although the interview was after the date when it is alleged that the twelve scales embodying that feature were made and sold. Hoyt's explanation is that he did not wish to disclose the whole invention to Mauldin; but this is inconsistent with his announced purpose in making the disclosure. It was not necessary to make any disclosure at all if Hoyt did not wish to give the information, and it seems clear that a partial disclosure could not effect the purpose had in view in making it.

After all that they claim to have done and after having a knowledge of Mauldin's invention Swihart and his assignee did not file an application for a patent for a period of six months. This conduct, taken with the familiarity of Swihart and the officers of the company with patent matters, is peculiarly significant. The application seems to have been an afterthought, and Hoyt can give no explanation of the delay.

Although Swihart may have been the first to conceive the idea of using a dash-pot in a scale, the evidence taken as a whole fails to establish a reduction to practice of the specific matter of the issue until after Mauldin had completed the invention. The decision must therefore be in favor of Mauldin.

The decision of the Examiners-in-Chief is affirmed.

EX PARTE SPRINGBORN.

Decided March 15, 1902.

1. ACTION ON MERITS—RULE 64—PRACTICE.

When the invention can be understood, the case should receive action throughout on its merits. (Rule 64.)

2. CASE—CASE—CASE.

To merely state that there is patentable subject-matter presented in the application is not sufficient under the last clause of Rule 64 to warrant the Examiner in insisting upon formal requirements before the case receives action on its merits. Requirements in matters of form will be insisted upon only in those cases in which the examination on the merits is completed. The case, except for formal matters, must be ready for allowance or for appeal.

ON petition.

SELECTIVE PART-LINE TELEPHONE SYSTEM.

Application of Albert J. Springborn filed June 12, 1901, No. 64,808.

Mr. S. E. Fouts for the applicant.

ALLEN, Commissioner.

This is a petition from the action of the Examiner.

No. 3.]

insisting upon his requirement for further illustration of this invention before acting on the merits of the case.

It is therefore prayed that the Examiner be advised that his requirement for further illustration be not insisted upon and that he be directed to proceed with the examination of the claims on their merits.

Rule 64 provides:

64. Where the specification and claims are such that the invention may be readily understood, the examination of a complete application and the action thereon will be directed throughout to the merits; but in each letter the Examiner shall state or refer to all his objections.

Only in applications found by the Examiner to present patentable subject-matter and in applications on which appeal is taken to the Examiners-in-Chief will requirements in matters of form be insisted on. (See Rules 95 and 184.)

The Examiner bases his action on two grounds—first, that the specification and claims cannot, in his opinion, be readily understood, because the illustration is not sufficiently clear and distinct to enable him to make an intelligent examination on the merits, and, second, that patentable subject-matter is claimed and that certain of the claims (not specified) are allowable, of which fact the petitioner has been officially informed in the Office letters.

The Examiner holds that his first ground is warranted by the provision of the first clause of Rule 64 and that the second ground is warranted by the provision of the last clause of said rule.

With respect to the second ground the Examiner is in error. The statement in the last clause of Rule 64 means that requirements in matters of form will be insisted upon only in those cases in which the examination on the merits is completed. The case, except for the formal matters, must be ready for allowance or for appeal and said appeal must have been taken. To merely state that there is patentable subject-matter presented in the application is not sufficient under the last clause of Rule 64 to warrant the Examiner in insisting upon formal requirements before the case receives action on its merits. When the invention can be understood, the case should receive action throughout on its merits. If it cannot be understood, it is of course impossible to act on the merits. It follows that the practice followed by the Examiner was correct under the first clause of Rule 64 if the disclosure was such that the invention could not be understood.

A careful reading of the specification in connection with the drawing as now filed renders the invention capable of being clearly understood. The drawing is made on a smaller scale than usual; but from a careful study of the same in connection with the description thereof it is apparent that both have been intelligently and carefully prepared.

The invention is a complicated one and cannot of course be readily understood upon a mere inspection of the drawing. The drawing, however, is clear when read in connection with the specification, and the invention can be understood. The condition of this application warrants an action throughout on the merits, and it is so directed.

The petition is granted.

[Vol. 99. No. 8.]

EX PARTE MORLEY.

Decided March 12, 1901.

1. CITATION OF DECISION OF EXAMINERS-IN-CHIEF—REFERENCE TO ANOTHER PARTY'S APPLICATION.

Where in his answer to an appeal to the Examiners-in-Chief the Primary Examiner refers to a decision by that tribunal in regard to another pending application holding that a similar invention was not patentable, Held that the reference will be canceled from the answer.

2. SAME—SAME—ACCESS TO OTHER CASE DENIED.

An applicant should be fully informed of the reasons for rejection and given an opportunity to meet them, and therefore in the treatment of one case reference should not be made to another case filed by a different party to which the applicant cannot have access.

3. CITATION OF MANUSCRIPT DECISIONS—KNOWLEDGE OF INVENTION NECESSARY.

Manuscript decisions of the Examiners-in-Chief and of the Commissioner may be cited in support of some contention of law if it can be done without disclosing the applicant's invention or making it necessary for the party against whom they are cited to understand the inventions in order to appreciate the pertinence of the decisions to the matter under consideration.

ON petition.

VENTILATED MATERIAL FOR BOOT AND SHOE UPPIERS, ETC., AND METHOD OF MAKING THE SAME.

Application of Alfred J. Morley filed April 30, 1901, No. 58,381.

Messrs. Mann & Co. for the applicant.

ALLEN, Commissioner:

This is a petition that the Primary Examiner be directed to cancel from his answer to an appeal taken to the Examiners-in-Chief all reference to another application previously considered by that tribunal on appeal.

The claims in this case were rejected as lacking in patentable novelty in view of certain references cited, and the applicant took an appeal to the Examiners-in-Chief from that rejection. In his answer to that appeal the Examiner, after stating the reasons for the rejection of the claims, said:

In the case of *ex parte Powers*, appeal number 20,885, your honors passed upon this invention, the claim therefor having been rejected upon the state of the art shown in the patents to Evans, to Hughes, and the English patent to Goodyear, herein cited, your honors decided the *Powers* invention to be devoid of patentable novelty, in view of the state of the art cited.

The petitioner objects to this statement for several reasons, the principal one of which and the only one which it is necessary to here consider being that he has no right under the rules of the Office to see the *Powers* application or the decision rendered in regard to it.

It is undoubtedly true that under Rule 15 the petitioner has no right to see the *Powers* application, and in view of this rule the propriety of even the statement that such an application is on file is, to say the least, doubtful. The Examiner's statement in regard to the *Powers* case is of such a nature that the petitioner cannot intelligently answer it in argument without a knowledge of that case. It is necessary for him to know just what *Powers* discloses and claims. If, therefore, that case has any relevancy and can furnish a basis for a decision in this case, it is apparent that its interjection into the case without giving the petitioner an opportunity to intelligently answer it amounts to unfair treatment. It is one of the best-settled principles

of practice that an applicant shall be fully informed of the reasons for rejection and shall have ample opportunity to meet them. The impropriety of the Examiner's reference to the *Powers* case is therefore obvious.

Aside from the practical difficulty raised by Rule 15 to the citation of the actions of the tribunals of the Office in regard to unpatented cases, a correct understanding of which requires a knowledge of the cases, it is clear that a reference to the *Powers* case was not necessary in order to get before the Examiners-in-Chief the real grounds for the rejection of the claims in this case. If they sustain the Examiner's rejection in this case, it will be because they are of the opinion that the references cited anticipate the claims and not because they sustained his action in another case in regard to what he considers a similar invention.

While the decisions of the Examiners-in-Chief are authoritative and binding upon the Examiner, and although the ability to cite them might materially simplify the treatment of subsequent applications covering similar inventions, it is impossible by reason of Rule 15 to take advantage of them in the way attempted by the Examiner in this case.

It is not intended by this decision to hold that a manuscript decision of the Examiners-in-Chief or of the Commissioner cannot be cited in support of some contention of law if it can be done without disclosing the applicant's invention or making it necessary for the party against whom it is cited to understand the invention in order to appreciate the pertinence of the decision to the matter under consideration.

The petition is granted.

REECE & FENWICK.

Decided March 19, 1901.

1. INTERFERENCE—AMENDMENT—ADDITION OF NEW CLAIMS—CONSENT OF PARTIES.

Where before testimony is taken both parties by common consent wish to present certain claims as additional counts of the interference and file amendments embodying those claims, Held that the interference will be remanded to the Primary Examiner to determine if the claims are allowable and should be included in the interference.

2. SAME—SETTLING ALL QUESTIONS AT ONCE.

It is the general policy of the Office to have all questions which may be brought in issue between the parties settled in one interference where possible.

ON motion.

PILING—MACHINE.

Application of George Reece filed June 13, 1900, No. 20,125. Application of Albert D. Fenwick filed March 19, 1900, No. 9,302.

Messrs. Crosby & Gregory for Reece.

Mr. George N. Goodard for Fenwick.

ALLEN, Commissioner:

This case comes up on a motion signed by both parties asking that proceedings be suspended and the interference remanded to the Primary Examiner for the purpose of entering certain claims in each party's application and reforming the interference to include those claims as counts of the issue.

[Vol. 99.

This interference was declared on February 23, 1901, and the parties have not yet taken testimony or filed preliminary statements. The attorneys, however, after consultation have reached the conclusion that the parties are entitled to claims differing somewhat from the counts of the issue and that the inclusion of them in the interference would conduce to a more complete determination of the question of priority as to the common invention. Each party has therefore presented two new claims which he asks to have substituted for claims in the case before the interference is proceeded with.

These amendments do not come within the provisions of Rule 109, since the claims are not now contained in either application and have not been decided by the Examiner to be allowable. They do not strictly come within any of the rules in relation to the amendment of cases in interference. On the other hand, the reasons for the general rules against the amendment of cases in interference do not apply to the situation presented, where no testimony is taken and both parties are willing and desirous of having the claims considered at this time and made a part of the issue. There can be no question of delay contrary to the interest and wishes of one of the parties, and no confusion in taking testimony can result. These claims could, of course, be presented after the conclusion of the interference, and in so far as the work of the Office is concerned it is not of consequence when the examination of them is made. It is the general policy of the Office to have all questions which may be brought in issue between the parties settled in one interference, and it would seem to be to the interest of the parties and of the Office to have the question whether the proposed claims may constitute an issue in this case settled at this time rather than at the conclusion of the interference.

This case not being specifically provided for in the rules presents a situation properly calling for the exercise of the supervisory authority of the Commissioner. The motion is granted, and the interference is remanded to the Primary Examiner for the consideration of the amendments presented with instructions to reform the issue as requested in case he finds that the proposed claims are allowable to the parties.

EX PARTE COOPER.

Decided March 27, 1901.

SUBSTITUTE DRAWING—REFUSAL TO ADMIT.

Where the drawing in the case shows the invention clearly and properly, Held that a substitute drawing should not be admitted.

ON petition.

ARRANGEMENT OF THE MATTER OF NEWSPAPERS, ETC.

Application of Edwin James Cooper filed July 9, 1900, No. 28,066.

Mr. Cooper pro se.

ALLEN, Commissioner:

This is a petition from the action of the Examiner refusing to permit the substitution of a new drawing for that now in the case.

No. 3.]

It appears that the application is ready for issue. The claims cover a newspaper-page having a longitudinal folding space, while the specification states that while it is sometimes desirable to use both longitudinal and transverse folding spaces, yet the longitudinal space alone is sufficient. The drawing now in the case shows both spaces. Applicant, however, wishes to substitute for this a drawing showing only the longitudinal space.

It is evident that the drawing now on file shows the subject-matter of the allowed claims very clearly and that there would be no misconception as to the scope or meaning of the claims were the patent to issue with this drawing in place of the one now proposed.

On the other hand, if the new drawing were admitted it would necessitate a corresponding revision of the specification, entailing upon the Office much unnecessary work in the examination of the same. Under these circumstances the new drawing should not be admitted. (*Ex parte Pugh*, 96 O. G., 841.)

The petition is denied.

OLDHAM AND PADBURY v. PECK & CLEMENT & RICHARDS.

Decided April 3, 1902.

INTERFERENCE—MOTION—EXAMINER SHOULD DECIDE ALL GROUNDS.

Where a party made a motion to dissolve on all of the grounds mentioned in Rule 123 and the Primary Examiner decided only two of those grounds, *Held* on appeal that the case will be remanded to the Examiner with instructions to decide all grounds alleged.

ON MOTION.

PNEUMATIC TOOLS.

Application of Samuel Oldham and John J. Padbury filed April 12, 1901, No. 55,463. Application of Clarence W. Peck filed January 30, 1901, No. 45,344. Application of John F. Clement filed December 31, 1900, No. 41,636. Application of Charles B. Richards filed December 24, 1900, No. 41,005.

Mr. J. Walter Douglass for Oldham and Padbury.

Mr. Eugene Diven for Peck.

Messrs. Howson & Howson for Clement.

Mr. Wm. Secher for Richards.

ALLEN, Commissioner:

This case comes before the Commissioner upon a motion by Richards to extend the limit of appeal from a decision of the Primary Examiner upon motions to dissolve the above-entitled interference brought by Oldham and Padbury and by Clement.

The motion to dissolve brought by Oldham and Padbury was based upon all of the grounds specified in Rule 123, as follows:

1. That no interference in fact exists.
2. That there has been such irregularity in declaring the same as will preclude a proper determination of the question of priority.
3. That the three issues framed in the interference and each of them are not patentable subject-matter, in view of the prior state of the art; and
4. That Clarence W. Peck, John F. Clement and Charles B. Richards are neither of them entitled to make the claims in

[Vol. 99. No. 3.]

their respective applications said to be involved in this interference.

Clement's motion to dissolve was based upon the first two of the above-named grounds, and, further, upon the ground—that the applicant Charles B. Richards is not entitled to make the claims constituting the three several clauses of issue in said interference.

The Primary Examiner in his decision upon these motions found that no interference in fact exists between Richards and the other parties—

“... since Richards does not show, as set forth in counts 1 and 2, a valve ‘one face of which is opened to a chamber to which motive fluid under normal pressure is admitted,’ ... nor is there shown a ‘valve being actuated by direct air-pressure at one stroke of the piston,’ as set forth in count 3.”

The Primary Examiner found also that the issues were not anticipated by the prior art. Upon the question of the right of the respective parties named in the motions to make the claims and of irregularity in the declaration he made no decision. Richards then filed an appeal to the Examiners-in-Chief from this decision of the Primary Examiner; but upon motion by Peck this appeal was dismissed, the Examiners-in-Chief holding that they had no jurisdiction, since from a decision upon the question of interference in fact appeal lies directly to the Commissioner, while there is no appeal from a favorable holding upon the patentability of the issue. Richards thereupon brought the present motion to extend the limit of appeal and filed an appeal to the Commissioner from the Examiner's decision on the question of interference in fact.

The action of the Examiner in deciding the motions to dissolve on some of the grounds only was irregular. It is well settled that the Examiner should decide such motions on all the grounds upon which they are based, (*Hinkley v. Barker*, 97 O. G., 2743;) otherwise it might happen, as, in fact, it has happened in the present case, that a party would be deprived of his right to appeal.

It may be contended with some force that Richards has waived any irregularity in the Examiner's action, by which appeal to the Examiners-in-Chief on the question of his right to make the claims has been prevented, by filing an appeal to the Commissioner on the question of interference in fact; but it is clear from the Examiner's decision that the question of interference in fact is so connected with that of Richards' right to make the claims that the consideration of one necessarily involves the other. In view of the fact that the right of the parties to make the claims was one of the grounds upon which the motions to dissolve were based this question should be decided in the regular course by the Examiners-in-Chief before it is brought to the Commissioner.

This interference is therefore remanded to the Primary Examiner, who will decide the motions upon all the grounds upon which they are based in order that appeals may be taken in the regular course.

In view of this holding it is unnecessary to consider the motion to extend the limit of appeal. This motion is accordingly dismissed.

Revision of Trade-Mark Rules.

(Order No. 1,465.)

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., April 3, 1902.

Rule 21, subdivision (b.) governing the registration of trade-marks, is hereby amended to read as follows:

(b) A statement specifying name, domicile, location, and citizenship of the party applying; the class of merchandise and the particular description of goods comprised in such class to which the particular trade-mark has been appropriated; a description of the trade-mark itself, and a statement of the mode in which the same is applied and affixed to goods, and the length of time during which the trade-mark has been used, and if the applicant be a corporation it must set forth under the laws of what State or nation incorporated.

F. I. ALLEN,
Commissioner.

Amendment of Section 4883, Revised Statutes, Relating to the Signing of Letters Patent.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., April 12, 1902.

By the act approved April 11, 1902, section 4883, Revised Statutes, has been amended to read as follows:

Sec. 4883. All patents shall be issued in the name of the United States of America, under the seal of the Patent Office, and shall be signed by the Commissioner of Patents, and they shall be recorded, together with the specifications, in the Patent Office in books to be kept for that purpose.

F. I. ALLEN,
Commissioner.

Roster of Registered Attorneys.

An alphabetical list of the individuals and firms registered in this Office under the provisions of Rule 17 of the Rules of Practice, as amended August 6, 1897, corrected to January 2, 1902, has been published, and copies will be furnished at the price of ten cents each, two five-cent coupons being acceptable in payment therefor.

Registrants are requested to give notice of any errors that appear in the list as published or any change of address since the list was prepared for publication.

Any solicitor, agent, or attorney who, in circulars or advertisements or otherwise, refers to the Commissioner of Patents, or to any other official of the Patent Office, for evidence of his professional standing, does so without authority.

Classification of Inventions.

A classification of patented inventions by classes and subclasses, with the number of patents in each subclass, revised to January 1, 1902, has been published in pamphlet form, paper covers. Copies may be obtained for 10 cents each.

Money by Mail.

Money sent by mail to the Patent Office will be at the risk of the sender. Letters containing money should be registered.

PATENTS

GRANTED APRIL 22, 1902.

697,959. LENS SYSTEM. ROBERT ARNT, Jena, Germany, assignor to The Firm of Carl Zeiss, Jena, Germany. Filed Dec. 22, 1899. Serial No. 728,052. (No model.)

Claim.—In lens systems for producing optical images of wide angle the combination with an aperture-diaphragm of a lens having a surface of revolution, the curvature of which surface gradually varies from the vertex to the margin, and which surface is so distant from the center of the aperture-diaphragm that it is traversed by the oblique pencils at other parts than by the axial pencil, essentially as described.

697,960. METALLIC ENVELOPE-CLOSURE. GEORGE E. ADAMS, New Britain, Conn. Filed May 21, 1891. Serial No. 62,611. (No model.)

Claim.—1. An improved envelope-fastener consisting of an eyelet having a flange with two prongs formed integral with said flange but located on opposite sides of the eyelet and projecting in opposite directions in the same plane as the flange of the eyelet, said eyelet being adapted to be secured to the body of the envelope under its closing-flap with the prongs lying flat against the outer face of the envelope; substantially as described.

2. An improved envelope-fastener consisting of an eyelet having a flange with two prongs formed integral with said flange but located on opposite sides of the eyelet and projecting in opposite directions, the flange of the eyelet and base of the prongs being cut to reduce the base of the prongs and extend said base within the circumference of the flange, substantially as described.

3. An improved envelope-fastener consisting of an eyelet having a flange with two prongs formed integral with said flange but located on opposite sides of the eyelet and projecting in opposite directions in the same plane as the flange, the base of the prongs extending within the circumference of the flange of the eyelet, whereby when the prongs are bent up they will lie within the circumference of the flange, substantially as described.

697,961. DEVICE FOR APPLYING AND REMOVING ELECTRIC LIGHT BULBS. LEO E. ARNOLD, Philadelphia, Pa. Filed Aug. 2, 1901. Serial No. 71,276. (No model.)

Claim.—1. A device of the character described, comprising an open-ended tubular socket having a plurality of longitudinal incisions formed

in one end thereof and dividing said end into integral spring-fingers which are bowed outwardly to form a cage or basket, a collar or band snugly embracing the base of the fingers on the outside of the socket and the adjacent portion of the socket, and a handle fitted into the other end of the socket.

2. A device of the character described, embodying a plurality of spring-fingers arranged to form a cage or basket, and protective casings embracing the respective fingers and projected beyond the outer ends thereof.

3. A device of the character described, embodying a plurality of spring-fingers arranged to form a cage or basket, and rubber tubular casings snugly fitting the respective fingers and projected beyond the outer ends thereof, each of said projected ends having its sides connected to form a projected buffer.

4. A device of the character described, embodying an open-ended tubular metallic socket, the lower end of which is constructed for engagement with a handle, and the upper end being provided with a plurality of longitudinal incisions to form fingers, which are bowed outwardly and are of arcuate shape to form a cage or basket, an inverted frusto-conical band or collar applied externally to the socket from the lower end thereof and snugly embracing the base of the fingers and the adjacent end portion of the socket, and soldered thereto, and rubber tubular casings snugly embracing the fingers and having their outer ends projected beyond the outer ends of said fingers, the projected end of each casing having its opposite sides mutually connected.

5. A device for applying and removing electric-light bulbs, comprising a handle having one end provided with a plurality of longitudinal outwardly-bowed flat spring-fingers disposed in a circular series to form a cage or basket of substantially the shape of an electric-light bulb, and rubber tubular casings snugly embracing the fingers and having their outer ends projected beyond the free ends of the fingers, the projected end of each casing having its opposite sides mutually connected to cover the outer end of the finger, for the purpose described.

697,962. RAIL-BOND. JORAN M. ANDERSON, Boston, Mass., assignor of one-half to Albert Anderson, Boston, Mass. Filed Feb. 12, 1902. Serial No. 66,278. (No model.)

Claim.—1. In a rail-bond, the combination with a bonding-conductor, of a bond-terminal comprising cooperating members normally separated for the reception of the bonding-conductor and one of which is provided with a locking projection to engage said bonding-conductor when said members are secured in their closed position, substantially as described.

2. In a rail-bond, the combination with a bonding-conductor, of a bond-terminal comprising two members between which said bonding-conductor is secured, one of said members having a flange projecting from one face and a base from its opposite face, and the other member having a locking projection adapted to be engaged by the bonding-conductor and in lock the same against longitudinal movement, substantially as described.

3. In a rail-bond, the combination with a bond-terminal having a base provided with a threaded opening, the threads of which comprise three of unequal length, the longer three extending in the direction of the length of the said opening, of a screw or bolt having a threaded shank, the threads of which are composed of three of unequal length, the longer three extending in the direction of the length of the shank and cooperating with the longer three of the thread in the opening in the base, substantially as and for the purpose specified.

4. A head-terminal for rail-bonds made in a single piece and comprising two members normally open or separated at one end, one of said members having a flange projecting from one face and a beam or projection extended from the opposite face, and the other member having a locking projection or lug on its face adjacent to the first member, substantially as described.

5. In a rail-head, the combination with a head-terminal comprising two members, one of which has a flange projecting from one face and a beam projecting from the other face and provided with an opening having an expanding screw-thread composed of faces of unequal length, and the other member having a locking projection or lug, of a screw or bolt having a shank provided with an expanding screw-thread composed of faces of unequal length which cooperate with the screw-threaded opening in said beam, substantially as described.

697,968. MAGNETO-ELECTRIC GENERATOR. VERNER S. AYER.
Dayton, Ohio. Filed May 2, 1901. Serial No. 53,486. (No model.)

Claim.—1. In a magneto-electric machine the combination of a revolving, multipolar, field-magnet with a stationary ring-armature within which it revolves, said armature consisting of an annular core having internal projections, said projections consisting of one or more plates of permanently-magnetized steel having outwardly-projecting poles of alternating polarity, and a means for laterally moving said field-magnet with reference to the armature, for the purpose of regulation, substantially as set forth.

2. In a magneto-electric machine the combination of a revolving, multipolar, field-magnet with a stationary, ring-armature within which it rotates, said armature consisting of an annular core made up of a series of thin laminations, having internally-projecting poles, coils wound between said projections, said field-magnet consisting of a series of disks, or plates, of permanently-magnetized steel, outwardly-projecting poles of alternate polarity, of short length, with reference to the diameter of the disk, a centrifugal governing device for separating the field-magnet from the armature, and a spring for returning said field-magnet to its normal position, substantially as set forth.

697,964. MILL FOR ROLLING ZAPFER'S ROLLER. HUBBARD.
HARRIS, Cleveland, Ohio. Filed Mar. 2, 1900. Renewed Aug. 20, 1901. Serial No. 73,851. (No model.)

Claim.—1. In a rolling-mill, the combination with a stationary roll, a movable roll, feed-covers for said movable roll, and mechanism connecting said covers to the roll-driving mechanism and constructed to operate said covers to feed the movable roll toward and from the stationary roll in unison with the rotation of the rolls, of a clutch device in said connecting mechanism, adjustable steps connected to travel with the movable roll, and a device for throwing out said clutch device and provided with actuating-triggers in the path of said adjustable steps, substantially as set forth.

2. In a rolling-mill, the combination with a stationary roll and a movable roll, of feed-covers for said movable roll, level-gears connected to rotate said covers, a shaft having bevel-gears engaging said former gears and having a sprocket-wheel, a shaft having two sprocket-wheels, a chain passing around two of said latter wheels and said former wheel, a shaft having a gear loose upon it and engaging a gear upon the stationary-roll shaft and having a sprocket-wheel, a chain passing around said latter wheel and the other of said former wheel, a friction-clutch upon said former shaft and engaging the gear upon the same, a hand-lever engaging said clutch, a bell-crank trigger and a trigger-lever upon the roll-bench, a bell-crank having one arm movably connected to the bell-crank trigger and the other arm connected to the trigger-lever by a link,

a spring for returning the bell-crank to its normal position, a hand-lever pivoted to the bell-crank and bell-crank trigger and having a notch engaging the hand-lever, and two stop-arms pivoted upon the bar of the movable roll and having means for adjusting them and projecting to engage the bell-crank trigger and the trigger-lever at the down and up strokes of the movable roll, substantially as set forth.

697,965. PISTON. EDWIN E. BALDWIN, Braintree, Mass. Filed May 2, 1901. Serial No. 54,591. (No model.)

Claim.—1. The combination with a cylinder having a port therein; of a reciprocating trunk-piston overrunning said port and having a spring-pressed plate mounted in the same side thereof as said port, said plate extending longitudinally of said piston and controlling said port, substantially as described.

2. The combination with a cylinder having a port therein; of a reciprocating trunk-piston overrunning said port and having a recess extending longitudinally thereof upon the same side as said port; a plate within said recess; and means, as springs, within said recess engaging the said plate for holding the same against the interior of said cylinder, the said plate controlling said port during the reciprocation of said piston, substantially as described.

3. The combination with a cylinder 1 having a port therein; of a reciprocating piston 7 provided with a longitudinal recess 13 upon the same side thereof as said port; a yielding plate 15 within said recess adapted to cover and uncover said port during the reciprocation of said piston; and springs 16 bearing against said plate, all constructed and operating substantially as described.

697,966. VEHICLE FRAME OR RUNNING-GEAR. ARTHUR B. BELL, New York, N. Y., assignor, by direct and mesne assignments, to Hester Vehicle Company. Filed Apr. 6, 1901. Serial No. 54,592. (No model.)

Claim.—1. In a vehicle frame or running-gear, the combination with

a fifth-wheel comprising an upper and a lower member, the upper member having backwardly-extending bifurcated projections; and a rear axle and device attached thereto having forwardly-extending bifurcated projections; of reaches, each comprising a T-iron and a rod or bar shorter than said T-iron and provided with a longitudinal channel or recess; the stem or leg of said T-iron at its ends being inserted between the bifurcated ends of the said projections respectively and between its ends being inserted in the channel or recess of the said rod or bar; and means for securing the ends of said reaches to said projections respectively.

2. In a vehicle frame or running-gear, the combination with a fifth-wheel comprising an upper and a lower member, the upper member having backwardly-extending bifurcated projections; and a rear axle and device attached thereto having forwardly-extending bifurcated projections; of reaches, each comprising a T-iron and a rod or bar shorter than said T-iron and provided with a longitudinal channel or recess; the stem or leg of said T-iron at its ends being inserted between the bifurcated ends of the said projections respectively and between its ends being inserted in the channel or recess of the said rod or bar; and bolts passing through said bifurcated ends of said projections and through the ends of said T-irons inserted between the same.

3. In a vehicle frame or running-gear, the combination with a fifth-wheel comprising an upper and a lower member, the upper member having backwardly-extending bifurcated projections; and a rear axle and device attached thereto having forwardly-extending bifurcated projections; of reaches, each comprising a T-iron and a rod or bar shorter than said T-iron and provided with a longitudinal channel or recess; the stem or leg of said T-iron at its ends being inserted between the bifurcated ends of the said projections respectively and between its ends being inserted in the channel or recess of the said rod or bar; and means for securing the ends of said reaches to said projections respectively, comprising sleeves or bands embracing the contiguous ends of said projections and reaches and bolts passing through said sleeves, bifurcated projections, and ends of the T-irons inserted therein, and bolts passing through said sleeves and the ends of the reaches inserted therein.

4. In a vehicle frame or running-gear, the combination with a fifth-wheel comprising an upper and a lower member, the upper member having backwardly-extending bifurcated projections; a duplex rear axle, comprising two middle portions approximately parallel and horizontal for part of their length but bent downward and toward each other at their ends, and end pieces or castings having laterally-projecting axle-spindles adapted to receive wheels; and two-part castings or clamps transversely grooved to receive said duplex axle between them and bolted thereto and provided with forwardly-extending bifurcated projections; of reaches, each comprising a T-iron and a rod or bar shorter than said T-iron and provided with a longitudinal channel or recess; the stem or leg of said T-iron at its ends being inserted between the bifurcated ends of the said projections respectively and between its ends being inserted in the channel or recess of the said rod or bar; and means for securing the ends of said reaches to said projections respectively.

5. In a vehicle frame or running-gear, the combination with a fifth-wheel comprising an upper and a lower member, the upper member having backwardly-extending bifurcated projections; a duplex rear axle, comprising two middle portions approximately parallel and horizontal for part of their length but bent downward and toward each other at their ends, and end pieces or castings having laterally-projecting axle-spindles adapted to receive wheels; and two-part castings or clamps transversely grooved to receive said duplex axle between them and bolted thereto and provided with forwardly-extending bifurcated projections; of reaches, each comprising a T-iron and a rod or bar shorter than said T-iron and provided with a longitudinal channel or recess; the stem or leg of said T-iron at its ends being inserted between the bifurcated ends of the said projections respectively and between its ends being inserted in the channel or recess of the said rod or bar; and bolts passing through said bifurcated ends of said projections and through the ends of the said T-irons inserted between the same.

6. In a vehicle frame or running-gear, the combination with a fifth-wheel comprising an upper and a lower member, the upper member having backwardly-extending bifurcated projections; a duplex rear axle, com-

prising two middle portions approximately parallel and horizontal for part of their length but bent downward and toward each other at their ends, and end pieces or castings having laterally-projecting axle-spindles adapted to receive wheels; and two-part castings or clamps transversely grooved to receive said duplex axle between them and bolted thereto and provided with forwardly-extending bifurcated projections; of reaches, each comprising a T-iron and a rod or bar shorter than said T-iron and provided with a longitudinal channel or recess; the stem or leg of said T-iron at its ends being inserted between the bifurcated ends of the said projections respectively and between its ends being inserted in the channel or recess of the said rod or bar; and means for securing the ends of said reaches to said projections respectively, comprising sleeves or bands embracing the contiguous ends of said projections and reaches and bolts passing through said sleeves, bifurcated projections, and ends of T-irons inserted therein, and bolts passing through said sleeves and the ends of the reaches inserted therein.

7. In a vehicle frame or running-gear, the combination with a duplex rear axle provided with axle-spindles; two-part castings or clamps transversely grooved to receive said duplex axle between them and secured thereto; and a fifth-wheel comprising an upper and a lower member pivotally secured together; of reaches secured to said casting or clamp and to the upper member of said fifth-wheel.

8. In a vehicle frame or running-gear, the combination with a duplex rear axle provided with axle-spindles; two-part castings or clamps transversely grooved to receive said duplex axle between them and secured thereto; and a fifth-wheel comprising an upper and a lower member pivotally secured together said lower member provided with a wheel-fork; of reaches secured to said casting or clamp and to the upper member of said fifth-wheel.

9. In a vehicle frame or running-gear, the combination with a duplex rear axle provided with axle-spindles; a fifth-wheel comprising an upper and a lower member pivotally secured together, the upper member being provided with elevated lateral projections adapted to support a spring secured thereto; and a fork secured to the lower member of said fifth-wheel; of reaches secured to said duplex axle and to the upper member of said fifth-wheel.

10. In a vehicle frame or running-gear the combination with a duplex rear axle provided with axle-spindles; a fifth-wheel comprising an upper and a lower member pivotally secured together, the upper member being provided with elevated lateral projections adapted to support a spring secured thereto; and a fork secured to the lower member of said fifth-wheel; of reaches secured to said duplex axle and to the upper member of said fifth-wheel, comprising a T-iron and a rod or bar having a longitudinal channel or recess.

11. In a vehicle frame or running-gear the combination with a duplex rear axle provided with axle-spindles, said axle having secured thereto two-part castings or clamps having forwardly-extending bifurcated projections; a fifth-wheel comprising an upper and lower member pivotally secured together, the upper member being provided with forwardly-extending bifurcated projections, and elevated lateral projections adapted to support a spring secured thereto; and a fork secured to the lower member of said fifth-wheel; of reaches comprising a T-iron and a rod or bar having a longitudinal channel or recess, the said T-iron being inserted in said channel or recess and projecting ends of the same being inserted in the said bifurcations and there secured.

697,967. WITHDRAWN

697,968. INTERIOR JUNCTION LINE OF STEEL RAIL-ROAD. WILLIAM B. BELL, Brooklyn, N. Y. Filed Aug. 20, 1901. Serial No. 73,852. (No model.)

Claim.—1. A space for justifying lines of matrices consisting of two reversible and interchangeable oppositely-bored wedges removably connected together, substantially as described.

2. In a space for justifying lines of matrices, the combination with two oppositely-bored wedges of a device removably connecting said wedges and positioned above or below the line of matrices, substantially as described.

3. In a space for justifying lines of matrices, the combination with two oppositely-bored wedges, of device removably connecting said wedges and positioned above and below the line of matrices, substantially as described.

4. In a space for justifying lines of matrices, the combination of a wedge having a beveled lower face and an outer face which is in one part perpendicular to the matrix-line and in one part parallel to said beveled face, another wedge having a beveled lower face and an outer face perpendicular to the line of matrices, and device removably connecting said wedges and positioned above and below the line of matrices substantially as described.

5. The combination with a matrix-line holder having end pieces which define the length of the justified line, and matrices, of a justifying-space consisting of two reversible and interchangeable oppositely-beveled and removably-connected wedges, substantially as described.

6. The combination with means for distributing and assembling matrices and spaces, of a holder for the line of matrices provided with jaws which determine the length of the line, matrices, and a justifying-space consisting of two reversible and interchangeable oppositely-beveled wedges, and devices removably connecting said wedges and positioned above and below the said holder, substantially as described.

7. A reversible interchangeable wedge constituting a member of a space for justifying lines of matrices and provided with a device for connecting said wedge with a similar reversed wedge above or below the line of matrices, substantially as described.

8. A reversible interchangeable wedge constituting a member of a space for justifying lines of matrices and provided with means for connecting said wedge with another similar wedge above or below the matrix-line and with a surface adapted to be engaged by connecting means on the other wedge, substantially as described.

9. The combination in a justifying-space, of two similar reversible and interchangeable wedges, each wedge having means for connecting with the other wedge above or below the matrix-line and a surface parallel with the meeting faces of said wedges and adapted to be engaged by the connecting means on the other wedge, substantially as described.

697,969. PHOTOGRAPH OR GRAPHOPHONE. CLARENCE BUTTER
New York, N. Y. Filed May 2, 1900. Serial No. 10,281. (No model.)

Claim.—1. In a photograph or like mechanism the combination with the mandrel for carrying the record-cylinder, of a fixed bearing for one end thereof, a movable bearing for the other end, an arm carrying said movable bearing, a post 11, a bearing for said arm in the post 11, a post 12, a second bearing for said arm in the post 12, said latter bearing serving also for the propelling-screw 13, so that the bearing carried by this arm may be swung out of the way of the cylinder in a plane at right angles to the axis of the mandrel, and a spring for holding said movable bearing in engagement with the mandrel, substantially as set forth.

2. In a photograph or like mechanism the combination with the mandrel for carrying the record-cylinder, of a fixed bearing for one end thereof, a movable bearing for the other end, an arm carrying said movable bearing, a post 11, a bearing in said post for said arm, a post 12, a bearing for said arm in the post 12, said latter bearing serving also for the propelling-screw 13, so that the bearing carried by this arm may be swung out of the way of the cylinder in a plane at right angles to the axis of the mandrel, a spring for holding said movable bearing in engagement with the mandrel, said arm being provided with depressions in the side

thereof, an abutment on the pedestal to receive said arm, and springs upon said abutment between which the arm rests and which enter the said depressions to hold the arm in place.

3. In a photograph or like mechanism, the combination with the back-rod above, of the speaker-arm formed integrally therewith and projecting forwardly therefrom in an arch over the record-cylinder and then curved to the right and terminated in a rest or support for the recorder or reproducer, a projection arising from said above, a frame carrying the diaphragm and apparatuses movably secured in said projection, an adjusting-pin in the forward end of said frame resting freely upon and unattached to said support, for the purpose set forth.

4. In a photograph or like mechanism the combination with the mandrel of the record-cylinder having a driving-pulley thereon, of a speed-indicator consisting of a ball-governor mechanism hinged to the base of the photograph, a friction-wheel on the arbor carrying the balls of the indicator, a spring for holding said wheel in engagement with the pulley on the mandrel of the record-cylinder, a scale, and a pointer actuated by the sliding sleeve of the ball-governor mechanism, for the purpose set forth.

5. The combination with the diaphragm and apparatuses, of the speaker-arm provided with the back-rod above on its rear end and with a rest upon its forward or free end, the frame carrying the diaphragm and apparatuses and movably secured to the back-rod above, and an adjusting-pin in the forward end of said frame by which said forward end is supported freely upon said rest and unattached thereto.

697,970. DRAFT-GAGE. KARL ROSEBAUM, Als-la-Chapelle, Germany. Filed Feb. 26, 1901. Serial No. 42,991. (No model.)

Claim.—1. A draft-gage comprising a receptacle with a central tube, a double-walled, vertically-guided and vertically freely moving bell provided with a chamber for the reception of the upper mouth of said central tube; a housing secured to said receptacle; a plunger revolvably secured to said housing; a rack secured to the top of said bell for transmitting the vertical motion of it to said plunger; and a pointer carried by said plunger to make the vertical motion of said double-walled bell visible upon a scale.

2. In a draft-gage as described the combination of a receptacle having a central tube and containing a sealing liquid with a double-walled vertically-moving bell containing a chamber normally surrounding the upper mouth of said tube; a housing secured to said receptacle; a plunger revolvably secured to said housing and carrying a pointer to visibly indicate upon a scale the vertical motion of said double-walled bell; a rack secured to the top of said bell and meshing with said plunger and means for guiding said bell and the rack, substantially as specified.

697,971. ENVELOPE. SAMUEL A. BUSHAFER, Erie, Pa. Filed Feb. 1, 1900. Serial No. 10,214. (No model.)

Claim.—1. As a new article of manufacture, a pair of integral envelopes, one of which is wholly inclosed within the other, the outer envelope having a detachable marginal strip, the removal of which will sever the envelopes from each other, and at the same time open the outer envelope and permit the removal of the inner envelope.

2. As a new article of manufacture, a pair of integral envelopes, one of which is wholly inclosed within the other, the folding-line between the two envelopes being midway between two rows of perforations which allow when the envelopes are finished and form a detachable strip, the re-

moval of which severs the envelopes from each other, and at the same time opens the outer envelope and permits the removal of the inner envelope.

3. As a new article of manufacture, an envelope having an inclosed integral portion, said envelope and inclosure having an integral detachable marginal strip for opening the envelope and for covering the same from said inclosure.

4. An envelope-blank comprising a sheet of paper divided by folding-lines into central portions and marginal flaps for the formation of two complete envelopes, the main folding-line between the two envelope-sections being located midway between two parallel rows of perforations and the removable strip thus formed between the two rows of perforations being so disposed as to form a marginal sealing-flap for one envelope, and a connecting-strip between the two envelope-sections.

5. As a new article of manufacture, an envelope-blank having a central folding-line 5 dividing the blank into two main sections, two parallel rows of perforations 11 and 23 being formed in the blank on opposite sides of the folding-line, thereby to form a detachable strip which may be removed to sever the envelopes without destroying the integrity of the smaller envelope, said blank being so shaped as to form two complete envelopes of different size.

697,972. METHOD OF PRODUCING SOFT-METAL CASTINGS. GEORGE H. BRANSON, Thornton, Mass. Filed Aug. 27, 1901. Serial No. 73,506. (No specimens.)

Claim.—1. The method of producing a casting of soft metal, which consists in impregnating the inner surface of a porous non-metallic mold with a vegetable-fat acid and running in the molten metal.

2. The method of producing a casting of soft metal, which consists in impregnating the inner surface of a porous non-metallic mold with palmitic acid as contained in the substance known as Japan wax, and running in the molten metal.

697,973. CAN-FLANGING MACHINE. JULIUS BRENNEMANN, New York, N. Y., assignor to MAX ARN, New York, N. Y. Filed Aug. 31, 1901. Serial No. 73,516. (No model.)

Claim.—1. A can-flanging machine having a removable work-holding frame, composed of a pair of hinged sections, a catch for closing the frame, and teeth on the periphery of the frame, substantially as specified.

2. In a can-flanging machine, the combination of a flanged can adapted to support the ends of a blank, with a frame embracing the blank, and with a wheel adapted to force the can-body inwardly between the ends and simultaneously rotate the same, substantially as specified.

3. A can-flanging machine provided with a flanged sleeve, a removable toothed work-holding frame adapted to be mounted thereon, a gear-wheel, and means for throwing the frame into and out of engagement with said wheel, substantially as specified.

4. A can-flanging machine provided with a shaft, a flanged sleeve mounted thereon, a removable toothed work-holding frame adapted to be mounted upon the sleeve, a gear-wheel, and means for throwing the frame into and out of engagement with said wheel, substantially as specified.

5. A can-flanging machine having a power-shaft, a counter-shaft, an intervening clutch, a cam on the counter-shaft, an arm oscillated by the cam, a shaft movable with the arm, a flanged sleeve rotatable upon the shaft, a work-holding frame adapted to be suspended from the sleeve, and a wheel adapted to engage said frame, substantially as specified.

6. A can-flanging machine having a power-shaft, a counter-shaft, an intervening clutch, a cam on the counter-shaft, a pair of arms oscillated by the cam, means for adjusting the arms, a buffer between the arms, a shaft movable with the arms, a flanged sleeve upon the shaft, a toothed work-holding frame, and a toothed wheel adapted to engage said frame, substantially as specified.

697,974. BASE-PIN FOR EXPLOSIVE PROJECTILES. CLARENCE E. BACCHUS, Windsor, Conn. Filed June 10, 1901. Serial No. 66,121. (No model.)

Claim.—1. A base-pin for a projectile consisting of a hollow body closed at one end by a primer-cap and containing a movable sleeve with an interior groove, a movable plunger with an exterior groove, and a yielding ring arranged to normally prevent the relative longitudinal movement of the plunger and sleeve and to be forced into the two grooves so as to lock the sleeve and plunger together by the backward movement of the sleeve, substantially as specified.

2. A base-pin for projectiles consisting of a hollow body closed at one end by a primer-cap and containing a movable sleeve, a movable plunger having sections of two different diameters with an exterior groove in the section having the larger diameter, and a yielding ring loosely located in a recess in the sleeve about the reduced part of the plunger so as to prevent the forward movement of the plunger until the sleeve is forced backwardly and forces the ring into the groove in the plunger and locks the plunger and sleeve together, substantially as specified.

3. A base-pin for projectiles consisting of a hollow body having a threaded exterior, a flanged head and a primer-cap closing one end, and containing a movable sleeve, a plunger with an exterior groove and a firing-pin, movable in the sleeve, and a yielding ring loosely located in a recess in the sleeve about a reduced part of the plunger so as to prevent the forward movement of the plunger until the sleeve is forced backwardly and forces the ring into the groove in the plunger and locks the plunger and the sleeve together, substantially as specified.

4. A base-pin for projectiles consisting of a hollow body having a threaded exterior, a flanged head, a primer-cap which occupies one end and is held in place by crimping the end of the body over the edge of the cap, said body containing a movable sleeve, a plunger with a firing-pin movable in the sleeve, an exterior groove in the plunger, and a yielding ring loosely located in a recess in the sleeve about a reduced part of the plunger and adapted to be forced into the groove in the plunger and expanded into the recess in the sleeve by the backward movement of the sleeve so as to lock the sleeve and plunger together, substantially as specified.

697,975. FOUNTAIN-PEN. FRANK C. BROWN, Brooklyn, N. Y. Filed Apr. 18, 1901. Serial No. 57,971. (No model.)

Claim.—1. In a fountain-pen, the combination of a feed-bar having two resilient tongues constituting feeds and adapted to receive a pen between them and a resilient brace adapted to bear upon the lower tongue with sufficient force to hold the pen and the two tongues firmly in contact.

2. In a fountain-pen, the combination of a feed-bar provided with two resilient tongues adapted to receive a pen between them and to constitute feeds, and an inclined resilient brace actuated in the feed-bar and adapted to bear firmly against the lower tongue in order to put the tongues under tension.

3. In a fountain-pen, the combination of a feed-bar provided with a plurality of tongues adapted to receive a pen between them in order to form feeds, and a removable resilient brace actuated in the feed-bar, the

aid brace exerting an upward pressure against the lower tongue of the feed.

4. In a fountain-pen, the combination with a feed of a feed-bar provided with a plurality of tongues adapted to receive a pen between them, the lower of said tongues being tilted and a flexible brace bearing against the said tilted tongue in such proximity to the tilt therein as to form with the said tilt a device for maintaining a reserve supply or body of ink.

5. In a fountain-pen, the combination of a longitudinally-movable feed-bar comprising a lower feed, the said lower feed being tilted, and a flexible brace bearing against the said lower feed and in such proximity to the tilt therein as to form with the said lower feed a device for maintaining a reserve supply of ink for the pen.

6. In a fountain-pen, the combination of a barrel which is in open communication with the air at all times, a pen-nib, a tilted under feed for the said pen-nib, a flexible brace bearing against the said under feed adapted to force the said under feed against the pen and to cooperate with the tilt in the under feed to maintain a reserve supply or body of ink in proximity to the pen.

7. In a fountain pen, the combination of a barrel having a contracted nozzle, a longitudinally-movable feed-bar contained within said barrel and furnishing an open communication with the outer air at all times, said feed-bar comprising a plurality of tongues, a pen-nib carried by the feed-bar and cooperating with the tongues, and means for preventing lateral movement of said feed-bar, said means consisting of projections extending from the feed-bar to a sliding engagement with the inner wall of the barrel.

8. In a fountain-pen, the combination of a pen-nib, two superposed feed-tongues on one side of the nib, and a third feed-tongue on the opposite side thereof.

9. In a fountain-pen, the combination of a pen-nib, a plurality of superposed feed-tongues beneath the pen-nib and the feed-tongues above the pen-nib.

10. In a fountain-pen, the combination of a longitudinally-movable feed-bar, a pen-nib carried by said feed-bar, a plurality of feed-tongues beneath said pen-nib and a feed-tongue above the same, said tongues being carried by and movable with the feed-bar and constituting part thereof.

11. In a fountain-pen, the combination of the feed or barrel, with a feed-tongue the inner surface of which is located in engagement with the nib or pen, and another feed-tongue the forward end of which engages the outer surface of the first-named feed-tongue.

12. In a fountain-pen, the combination of the barrel having an interior shoulder, with a feed-bar movable lengthwise of the barrel and provided with a shoulder arranged to engage that of the barrel, and with an end portion extending forwardly from said shoulder and carrying a writing member, the said two shoulders forming a valve-seat and a valve respectively, and means for preventing lateral movement of the feed-bar, said means consisting of projections extending from the feed-bar to a sliding engagement with the inner wall of the barrel.

13. In a fountain-pen, the combination of the feed or barrel with a feed-bar having spaced tongues adapted to receive a pen between them, and a brace carried by the feed-bar and extending to the outer surface of one of the tongues.

14. In a fountain-pen, the combination of the feed or barrel with a feed-bar having spaced tongues adapted to receive a pen between them, and a brace carried by the feed-bar and extending obliquely upward therefrom, the upper end of said brace being in engagement with the outer surface of the lower tongue.

15. The combination of a pen, a pen-carrier provided with a tongue adapted to feed ink to the under side of the pen, and a resilient brace adapted to bear against said tongue with sufficient pressure to hold the pen and tongue together and to hold a body of ink in proximity to the nib of the pen.

16. The combination of a pen and a pen-carrier provided with a plurality of tongues superposed on the same side of the pen which are adapted to feed ink to the pen and to hold a body of ink in proximity to the nib of the pen, the tongues lying adjacent to the pen being tilted.

17. The combination of a pen, a pen-carrier provided with a tongue adapted to feed ink to the under side of the pen, and a resilient brace adapted to bear on said tongue with sufficient pressure to hold the pen and tongue together and to hold a body of ink in proximity to the nib of the pen, said tongue being tilted longitudinally.

697,976. COMPOSITION FOR CLEANING METALS. VALLEY B. BROWN, Woodstock, N. H. Filed Sept. 25, 1901. Serial No. 75,687. (No specimen.)

Claim.—A metal-polishing compound consisting of the following ingredients in substantially the following proportions: calc-tallow, one and one-fourth pounds; gum-sassafras, three ounces; lavender, four ounces; rose linseed-oil, eight ounces; kerosene-oil, fifteen ounces; powdered tripoli, two pounds, and a suitable quantity of perfume.

697,977. PIPE-WRENCH. GEORGE W. BARNES, Brooklyn, N. Y., assignor to J. H. Williams and Company, Brooklyn, N. Y., a Corporation of New York. Filed Jan. 27, 1902. Serial No. 91,503. (No model.)

Claim.—1. A wrench, having, in combination, the body provided with a fixed jaw and a socket, a pivoted movable jaw having a bearing in rear of the pivot, a spring-actuated follower slightly arranged in the socket and contacting with the bearing during the movement of the pivoted jaw, the upper and lower limits of the range of movement of the upper end of said follower being respectively above and below the plane of the pivot, and within the arc described by the bearing during the movement of the jaw.

2. A pipe-wrench, having, in combination, a body terminating at its upper end in a fixed curved jaw, and provided at its rear edge with a longitudinally-arranged socket, a movable curved jaw provided with elongated depending ears taking over the lower jaw and extending down upon the body, a pivot passing through said ears and body, a spring-actuated follower slightly arranged in the socket and bearing at its upper end against the pivoted jaw at a point between the depending ears, the upper and lower limits of the range of movement of said follower being respectively above and below the plane of the pivot.

3. A wrench, having, in combination, a body terminating in a fixed jaw and provided with a socket, a movable jaw pivotally mounted on the body, a pivot therefor, a spring-actuated follower slightly mounted in said socket and having an exposed portion projecting upward therefrom and bearing at its end against the movable jaw in rear of the pivot, and guides for the exposed portion of the follower.

4. A wrench, having, in combination, a body provided with a fixed curved jaw and with a socket, a movable curved jaw pivotally mounted on said body, a pivot therefor, a spring-actuated follower slightly arranged in said socket and bearing at its upper end against the movable jaw in rear of the pivot, and curved guides for said follower located directly in rear of the pivot, with their rear edges concentric with said pivot.

5. A pivoted-jaw pipe-wrench, having, in combination, a body having a fixed jaw, a pivoted jaw on the body, and a spring-actuated follower carried by the body extending above and below the plane of the pivot and engaging the pivoted jaw.

6. A pivoted-jaw pipe-wrench, having, in combination, a body having a fixed jaw, a pivoted jaw on the body, a spring-actuated follower on the body extending above and below the plane of the pivot, and guides for the follower embracing the sides only thereof.

697,978. MACHINE FOR CUTTING BLANKS FROM FABRIC. JAMES A. GARDNER, Brooklyn, N. Y. Filed June 22, 1901. Serial No. 91,498. (No model.)

Claim.—1. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, the movable carriage mounted on said table and carrying clamping members to engage said fabric and said fabric down against said table at each side of the line of severance, and transverse guides for guiding said carriage, combined with a knife for effecting the severance of the fabric on a line intermediate said members and adapted to said members so as to be guided thereby; substantially as set forth.

2. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, and the movable carriage mounted on said table and having the pivoted arms and clamping-plates, said plates being carried at the inner ends of said arms, and said arms being of such length that when turned toward one another and to their lower position said plates will press against said fabric at each side of the line of severance, combined with a knife for covering the fabric on a line intermediate the adjoining edges of said plates; substantially as set forth.

3. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, and the movable carriage mounted on said table and having the pivoted arms and clamping-plates, said plates being carried at the inner ends of said arms, and said arms being of such length that when turned toward one another and to their lower position said plates will stand on downwardly-converging lines with their lower edges pressing against said fabric at each side of the line of severance, combined with a knife for covering the fabric on a line intermediate the adjoining edges of said plates; substantially as set forth.

4. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, and the movable carriage mounted on said table and having the pivoted arms and clamping-plates, said plates being carried at the inner ends of said arms, and said arms being of such length that when turned toward one another and to their lower position said plates will stand on downwardly-converging lines with their lower edges pressing against said fabric at each side of the line of severance, combined with a knife for covering the fabric on a line intermediate the adjoining edges of said plates; substantially as set forth.

5. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, and the movable carriage mounted on said table and having the pivoted arms and clamping-plates, said plates being carried at the inner ends of said arms and said arms being of such length that when turned toward one another and to their lower position said plates will stand on downwardly-converging lines with their lower edges pressing against said fabric at each side of the line of severance, combined with a knife for covering the fabric on a line intermediate the adjoining edges of said plates; substantially as set forth.

said knife having the blade, stock and handle, and said stock having downwardly-converging sides to fit against the facing surfaces of the said plates when the latter are in their lower position; substantially as set forth.

6. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, and the movable carriage mounted on said table and comprising the side bars 35, the standards 36 connected with said bars, the rods 37 connecting said standards, the pivoted arms 40, the bars 41 connecting said arms in pairs, the plates 42 secured to said bars 41, and the knife for detachably holding said bars, plates and arms in their inoperative position, said arms being of such length that when turned toward one another and to their lower position said plates will press against said fabric at each side of the line of severance, combined with a knife for covering the fabric on a line intermediate the adjoining edges of said plates; substantially as set forth.

7. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, the bars at the ends of said table over which the said fabric may be folded into a vertical series of longitudinal lengths, and means for restraining said bars against displacement under the strain of the folded fabric, combined with the movable carriage for said table, the transverse guides for guiding said carriage longitudinally of said table, clamping means carried by said carriage transversely over and adapted to bind down upon said vertical series of lengths of fabric along the predetermined transverse lines of severance, and a knife for cutting through said series of lengths of fabric along the line of said clamping means; substantially as set forth.

8. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, the pins or standards 17, 20, at the ends of said table, and the bars 18, 21, perforated at one end and closed at the other and to engage said pins or standards, said bars serving to determine the length of the folds in said fabric by being confined within the ends of said lengths, combined with the movable carriage for said table, the transverse guides for guiding said carriage longitudinally of said table, clamping means carried by said carriage transversely over and adapted to bind down upon said vertical series of lengths of fabric along the predetermined transverse lines of severance, and a knife for cutting through said series of lengths of fabric along the line of said clamping means; substantially as set forth.

9. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, the pins or standards 17, 20, at the ends of said table, and the bars 18, 21, perforated at one end and closed at the other and to engage said pins or standards, said bars serving to determine the length of the folds in said fabric by being confined within the ends of said lengths, combined with the movable carriage for said table, the transverse guides for guiding said carriage longitudinally of said table, clamping means carried by said carriage transversely over and adapted to bind down upon said vertical series of lengths of fabric along the predetermined transverse lines of severance, and a knife for cutting through said series of lengths of fabric along the line of said clamping means; substantially as set forth.

10. In a machine of the character described, the table upon which the fabric to be covered into sections or blanks may be placed, the pins or standards 17, 20, at the ends of said table, and the bars 18, 21, perforated at one end and closed at the other and to engage said pins or standards, said bars serving to determine the length of the folds in said fabric by being confined within the ends of said lengths, combined with the movable carriage for said table, the transverse guides for guiding said carriage longitudinally of said table, clamping means carried by said carriage transversely over and adapted to bind down upon said vertical series of lengths of fabric along the predetermined transverse lines of severance, and a knife for cutting through said series of lengths of fabric along the line of said clamping means; substantially as set forth.

11. In a machine of the character described, the table, means for enabling the folding thereof of the fabric into a vertical series of smooth longitudinal lengths of predetermined extent, movable clamping devices for pressing down and holding the fabric at each side of each predetermined line of severance, and a knife for covering the fabric and adapted to said clamping devices so as to be guided along the line of severance thereby; substantially as set forth.

12. In a machine of the character described, the table, means for enabling the folding thereof of the fabric into a vertical series of smooth longitudinal lengths of predetermined extent, the traveling carriage bearing the clamping-plates 43 for pressing down and holding the fabric at each side of each predetermined line of severance, said plates when in their lower position being on lines converging downward toward one another, combined with the knife for covering the fabric and having the stock whose opposite sides are adapted to the converging faces of said plates so as to be guided thereby; substantially as set forth.

697,979. DOCK. EDWARD P. GALT, Louisville, Ky. Filed June 1, 1901. Serial No. 68,703. (No model.)

Claim.—1. As an improved article of manufacture, a book provided on the surfaces exposed to view with distinguishing markings, especially arranged markings being placed side by side, some of the markings being at right angles to others, whereby one of the marks will always be exposed in an upright position, substantially as described.

2. As an improved article of manufacture, a book provided with distinguishing markings upon one of its edges, the markings being arranged in groups comprising marks inverted with respect to each other, some of the groups being at right angles to others so that one of said marks is always in position to be read, whereby the identity of the book can be readily ascertained, substantially as described.

3. As a new article of manufacture, a book provided with distinguishing marks on one of its edges, the said marks being arranged near the opposite corners of the book, and being reversed with respect to each other, and some of said marks being at right angles to others whereby one of said marks will always be exposed in an upright position, substantially as described.

4. A book provided on one of its edges with markings in duplicate sets, one set near one corner of the book and the other set near the opposite corner, each set consisting of two markings reversed in position with relation to each other and the two sets being duplicate in position and character, whereby when the book is laid down spread open one of the marks of the set will be exposed to view in an upright position, substantially as described.

5. A book provided with two sets of markings on its edges, each marking of each set being reversed in position with relation to the other mark of the set, and some of the groups being arranged to read longitudinally of the edge while other groups are arranged to read transversely of the edge, whereby some one of the marks will always be in an upright position, substantially as described.

6. A book provided with distinguishing marks arranged on the edges of its leaves, the marks being arranged in pairs, one of each pair being near one corner of the book while the other one of each pair is near the other corner of the book, and some of the pairs being at right angles to others so that some one of the markings will always be in an upright position as to be easily read, substantially as described.

697,980. AUTOMATIC MUSICAL INSTRUMENT. JULIUS CARPENTIER, Paris, France. Filed Dec. 17, 1900. Serial No. 40,107. (No model.)

Claim.—1. In a musical instrument, the combination of a series of movable parts, means for moving each of said parts from a normal to a displaced position, whereby various positions of said parts relatively to each other may be obtained, a series of sound-producing devices and means controlled by the relative positions of said moving parts for operating the individual sound-producing devices, whereby the latter are individually selected and sounded according to the different permutations of the displaced and unmoved parts.

2. In a musical instrument, a controlling means comprising a series of moving parts arranged approximately parallel to one another, and each movable from a normal to a displaced position, and having differently-spaced operative portions, whereby said operative portions shall be put into different operative relations as different groups of said parts are displaced, and sound-producing devices in operative relation to said controlling means, whereby the latter are individually selected and sounded according to the different permutations of the displaced and unmoved parts.

3. In a musical instrument, a controlling means comprising a series of moving parts arranged approximately parallel to one another, and each

movable from a normal to a displaced position, and having differently-spaced operative portions, whereby said operative portions shall be brought into alignment as different groups of said parts are displaced, and sound-producing devices in operative relation to said controlling means, whereby the latter are individually selected and sounded according to the different operative portions are brought into alignment by the movement of different groups of said parts.

4. In a musical instrument, the combination with a series of sound-producing devices and a means for generating air-pressure, of a transmitting or controlling mechanism connected to said means, comprising a plurality of plates having passages formed through them, said passages being disposed at different intervals in different plates, and means for moving groups of said plates to positions in which their passages may successively establish communication between said pressure-generating means and the individual sound-producing devices.

5. In a musical instrument, the combination with a series of sound-producing devices, and a means for generating air-pressure, of a transmitting or controlling mechanism connected to one side in such means, and at its other side to said devices separately, and comprising a plurality of plates, each movable from a normal to a displaced position, and having passages formed through it, said passages being differently spaced in the different plates so that by the movements of different groups of said plates from their normal to their displaced positions a connecting-passages is formed across said plates from said means to each of said sound-producing devices separately, and means for so moving groups of said plates.

6. In a musical instrument, the combination with a series of sound-producing devices, means for producing a flow of air through said devices, and an actuating mechanism for each of said devices adapted to connect it with said means, of a transmitting or controlling mechanism comprising a plurality of registers having passages formed through them, differently spaced in the different registers so that by moving said registers singly or in groups communication is cut off from all of the sound-producing devices except the single one which it is desired to actuate, and means for so moving said registers.

7. In an automatic musical instrument, the combination of a traveling sheet, a feed-roll for said sheet, means for depressing said roll to stop the feed of said sheet, and a series of fingers each adapted to be engaged by a part moving with said roll when the latter is depressed, whereby to disengage said fingers from said sheet when the latter is stopped.

8. In an automatic musical instrument, a means for controlling the air-pressure in two connected compartments, comprising a weighted valve, a piston connected to said valve, and a cylinder in which said piston moves.

697,981. CASH-REGISTER. THOMAS CANNON, Dayton, Ohio, assignor to the National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Aug. 17, 1900. Serial No. 27,104. (No model.)

Claim.—1. In a cash-register, the combination with a series of operating-segments arranged to be moved different distances and carrying

just, a series of nested sleeves supporting said arms and printing device connected to said sleeves.

3. In a cash-register, the combination with a series of operating-segments, of a series of dotted arms engaged by projections on said segments, nested sleeves operated by said arms, said segments carried by said sleeves, rack-bars meshing with said latter segments and carrying printing-types and printing device cooperating with said types.

4. In a cash-register, the combination with a series of operating-segments, of a series of dotted arms engaged by projections on said segments, nested sleeves operated by said arms, rack-segments carried by said sleeves, rack-bars meshing with said rack-segments and carrying types upon their upper and lower edges, and plates cooperating with the respective ends of types.

5. In a cash-register, the combination with a series of operating-segments, of a series of dotted arms cooperating therewith, a series of nested sleeves supporting said arms, rack-segments carried by said sleeves, a series of rack-bars meshing with said segments and carrying types upon their upper and lower edges, plates cooperating with the ends of types for respectively printing a detail-strip and a check and means for throwing the check-plates out of operative position at will.

6. In a cash-register, the combination with a series of operating-segments carrying anti-friction-rollers, of a series of dotted arms into which said rollers project, a series of nested sleeves supporting said arms, a series of rack-segments carried by said sleeves, a series of rack-bars meshing with said segments, and carrying types, a plate, and means for throwing said plate into and out of operative position.

7. In a cash-register, the combination with a series of operating-segments, of a series of dotted arms cooperating therewith, a series of nested sleeves supporting said arms, a series of rack-segments mounted on said sleeves, type-bars operated by said rack-segments, a slide carrying locking-arms, plates arranged to operate the locking-arms, a lever for moving the slide, and a cam connected to the movable parts of the machine for operating said lever.

8. In a cash-register the combination with a driving-shaft, of driven members arranged to be uncoupled from the driving-shaft by the keys, type-carriers, means connecting the carriers to the driven members, strip-feeding devices, a slide operating a knife and a cam on the driving-shaft for operating said slide.

9. In a cash-register, the combination with operating devices, of a printing mechanism comprising a series of types, locking-arms, a slide for operating said arms, plates for forcing said arms into contact with the types, means connected to the movable parts of the machine for operating said slide, a detail-strip feed-roller operated from said slide, means for operating the plates, and device for rendering one of the plates inoperative.

10. In a cash-register, the combination with a series of keys, of a driving member, driven rack members, device for coupling said segments to the driving member arranged to be tripped by the operated keys, anti-friction-rollers mounted on the rack-segments, pivoted arms having cam-ends into which said rollers project, type-carriers and nested sleeves connecting said arms and carriers.

11. In a cash-register, the combination with a series of keys, of a driving member, driven rack members, arranged to be uncoupled from the driving member by the keys, anti-friction-rollers mounted on the rack members, a series of nested sleeves, arms mounted on said sleeves and formed with cam-ends for the reception of the anti-friction-rollers, type-carriers and means connecting said sleeves and carriers.

12. In a cash-register, the combination with a series of keys, of a driving member, driven rack members arranged to be uncoupled from the driving member by the keys, pivoted dotted arms engaging projections on said rack members, type-carriers, and means connecting said arms and carriers.

13. In a cash-register, the combination with a series of keys, of a series of rack-segments, movable means mounted on said segments and arranged to engage an operated key to arrest the segment, a series of dotted arms, projections on the segments extending into the slots of said arms, a series of type-carriers and means connecting the dotted arms and carriers.

697,982. CASH-REGISTER. JAMES P. GRAY, Dayton, Ohio, assignor to the National Cash Register Company, Jersey City, N. J., a Corporation of New Jersey. Filed Mar. 3, 1900. Serial No. 7,125. (No model.)

Claim.—1. In a cash-register, the combination with a series of keys, of a detail having locking-notches for the same, a cash-drawer, and means for holding the detail so that its notches are out of alignment with the keys when the drawer is closed and in such alignment when the drawer is open.

2. In a cash-register, the combination with a series of keys provided with pins, of a detail having locking-notches for said pins, a cash-drawer,

and means intermediate the cash-drawer and detail whereby when the drawer is closed the locking-notches are held out of alignment with the pins but when the drawer is opened are moved into such alignment.

3. In a cash-register, the combination with a movable detail formed with locking-notches, of a series of keys radially mounted in respect to said detail so that when operated they become seated in said notches and exert a pressure directly toward the point of support of said detail and are thus locked against operation and means for moving the detail.

4. In a cash-register, the combination with a pivoted detail having a series of locking-notches, of a series of radially-arranged keys adapted when operated to become seated in said notches and exert a pressure toward the pivot of the detail, a cash-drawer and means intermediate the drawer and detail for adjusting the latter to bring the notches into the paths of the keys when the drawer is opened.

5. In a cash-register, the combination with a series of keys provided with laterally-projecting pins, of a pivoted detail having bevel projections formed with locking-notches and arranged to be engaged by said pins, a cash-drawer, and means intermediate the cash-drawer and detail whereby when the drawer is closed the locking-notches are held out of alignment with the pins but when the drawer is opened are moved into such alignment.

6. In a cash-register, the combination with a series of keys, of a detail having key-locking notches and a pendulum arm, and means operated by the cash-drawer and engaging said arm to move the detail so that the notches are out of locking position when the drawer is closed and in locking position when the drawer is open.

7. In a cash-register, the combination with a series of keys, of a detail arranged to be engaged by the keys and formed with retaining-notches and key-locking notches, the latter normally out of the paths of the keys, a cash-drawer and means intermediate said drawer and detail whereby when the drawer is opened the detail is moved to bring the locking-notches into the paths of the keys to lock the latter.

8. In a cash-register the combination with a series of keys, of a detail having key-locking notches which are normally out of the paths of the keys, a cash-drawer, a pivoted lever arranged to be operated by said cash-drawer and means intermediate said lever and the detail whereby the latter is operated to bring the notches into the paths of the keys to lock the same.

9. In a cash-register, the combination with a series of keys of a detail therefor having locking-notches which are normally out of the paths of the keys and also a pendulum arm, a cash-drawer, a pivoted lever engaging said arm, a pivoted lever arranged to be operated by the cash-drawer and a pivoted link connecting said levers, the construction being such that the notches are brought into the paths of the keys when the cash-drawer is opened.

10. In a cash-register, the combination with a series of keys having laterally-projecting pins, of a pivoted detail having locking-notches which cooperate with said pins, a pendulum arm mounted on said detail, a cash-drawer, a pivoted lever arranged to be engaged by the rear wall of said drawer, a pivoted lever engaging the pendulum arm, and a pivoted link connecting said lever.

11. In a cash-register, the combination with a pivoted detail having radial projections formed with locking-notches, of a series of radially-arranged keys adapted to cooperate with said projections and locking-notches, a cash-drawer and means intermediate said drawer and detail whereby the notches are held in alignment with the keys when the drawer is open.

12. In a cash-register, the combination with a movable detail having bevel-disk projections formed with locking-notches and retaining-notches, of keys having projecting pins which cooperate with said projections and notches and independent means for moving the detail to bring the locking-notches into the paths of said pins and thus prevent the depression of the keys.

13. In a cash-register, the combination with a movable detent formed with bevel-face projections having locking-notches, of a series of keys arranged to engage said projections and then move the detent, and independent means for moving the detent to bring the locking-notches into the path of the keys and then prevent the latter from being depressed.

14. In a cash-register, the combination with a series of keys, of a movable member formed with locking-notches and arranged to be operated by the movement of any key to allow the keys to become latched thereto, and a cash-drawer directly engaging said member to move it and bring the locking-notches into alignment with the keys to prevent the depression of the latter.

15. In a cash-register the combination with a series of keys, of a sliding detent, a series of projections arranged to retain an operated key in depressed position, said detent being given a limited movement whenever a key is depressed, of a cash-drawer and means controlled thereby for moving the detent into position to lock the unoperated keys of the series when the cash-drawer is opened.

16. In a cash-register the combination with a series of keys having lateral projections or pins, of a cooperating detent arranged to retain the operated keys in depressed position, a cash-drawer and means for moving the detent into position to lock the keys when the cash-drawer is opened.

697,988. ARTIFICIAL DENTURE. FRANK H. E. COCHRAN, Canal Winchester, Ohio. Filed Dec 7, 1901. Serial No. 86,061. (No model.)

Claim.—1. An artificial tooth, consisting of a body portion having substantially the shape of the natural tooth for which it is to be substituted and having that portion between the cervical border and the root or gum end of the tooth reduced in diameter, thereby forming at the cervical border an annular shoulder which faces toward the root or gum end of the tooth.

2. An artificial tooth, having substantially the shape of the tooth which it is to replace and provided at its cervical border with an annular shoulder extending entirely around the tooth and facing toward the root or gum end of the tooth, the portion of the tooth between this shoulder and the gum end being reduced in diameter and provided with a recess, as and for the purposes set forth.

3. In a dental bridge, in combination, a bridge consisting of an annular socket-band and means for attaching it to the permanent teeth, and an artificial tooth fitted in and supported by said socket-band, whereby the artificial tooth will be firmly supported all around and have a crown portion of substantially the shape and area of the natural tooth it is to replace.

4. In a dental bridge, the combination of a bridge consisting of an annular socket-band and means for attaching it to the permanent teeth, and an artificial tooth fitted in and extending through said socket-band and shouldered at its cervical border to abut against the edge of said socket-band entirely around it for the purposes set forth.

5. In a dental bridge, the combination of a bridge consisting of an annular socket-band of malleable metal, means for attaching it to the permanent teeth, and an artificial tooth fitted in and extending through said socket-band and shouldered to fit against one of its edges, said artificial tooth being provided with a recess and a portion of the metal socket-band being forced into said recess to lock the tooth in the socket-band.

6. In a dental bridge, the combination of a bridge proper consisting of two or more annular socket-bands cased together at their adjoining faces and provided with means for securing them to natural teeth in the mouth, and an artificial tooth fitted in and extending through each of said socket-bands, and means for supporting and locking said tooth in their respective socket-bands for the purposes set forth.

7. In a dental bridge, the combination of a bridge proper consisting of an annular socket-band, means for attaching said band to the adjacent natural teeth, and an artificial tooth having its root or gum end reduced in diameter and fitted in and extending through said band, the shoulder then formed at the cervical border by reducing the diameter of the tooth fitting against the edge of the socket-band all around, and means for fastening the tooth in said socket-band, for the purposes set forth.

697,984. ELECTRIC MOTOR. OLIVER F. GOSLIN and John L. Harvey, Dayton, Ohio. Filed Aug. 20, 1901. Serial No. 78,706. (No model.)

Claim.—1. In an electric motor, a casing comprising a cylindrical yoke having three threaded studs projecting from opposite sides thereof, heads including the sides of said yoke each of which has three openings

corresponding with the positions of the studs on the yoke, the said openings being surrounded on the inner sides of the heads by bosses which enable said heads to fit properly against the sides of the yoke, the openings in said heads and the studs on the yoke enabling said heads to be quickly and accurately placed in proper position on the yoke, substantially as specified.

2. In an electric motor, a motor-casing comprising a cylindrical yoke having three threaded studs projecting from opposite sides thereof, heads E and F each of which has three openings, the positions of which correspond to the positions of said studs, the said openings being surrounded on the inner sides of the heads by bosses for the purpose specified, the head E being provided with an integral cone-shaped clamp-bearing adapted to receive a journal-box, the head F being provided with a bracket projecting therefrom which terminates in a clamp-bearing also adapted to receive a journal-box, substantially as specified.

3. In an electric motor, the combination with a yoke having three screw-threaded studs projecting therefrom, of heads provided with three stud-openings surrounded by bosses on the inner sides of said heads, the said stud-openings being in line with the screw-threaded studs on the yoke, integral clamp-bearings projected from said heads, and journal-bones secured within said clamp-bearings, the said journal-bones having annularly-projected surfaces rounded in cross-section and which portions engage with the interior surfaces of said clamp-bearings, whereby the said journal-bones are permitted to adjust themselves to the proper axial diameter of the main shaft, substantially as specified.

4. In an electric motor, the combination with a yoke having three screw-threaded studs projecting therefrom, heads provided with three stud-openings surrounded by bosses on the inner sides of said heads, the said stud-openings being in line with the screw-threaded studs on the yoke, integral clamp-bearings projected from said heads, and journal-bones secured within said clamp-bearings, the said journal-bones having annularly-projected surfaces rounded in cross-section and which portions engage with the interior surfaces of said clamp-bearings, a rocker-arm clamped to one of said journal-bones, and brush-holders secured to said rocker-arm, all arranged substantially as specified.

5. In an electric motor, the combination with a yoke having an opening in the base thereof of uniform diameter, of a pole-piece having a shank or body portion of uniform diameter throughout and which is adapted to enter said opening in the yoke, the said shank or body portion being provided after the pole-piece has been adjusted to its proper position, and a screw adapted to penetrate laterally the yoke and enter the recess in said pole-piece, substantially as specified.

6. In an electric motor, the combination with a motor-yoke, of a single active pole-piece, the shank or body portion thereof being of uniform diameter throughout and adapted to enter an opening of similar diameter in the base of said yoke, means for securing said pole-piece in position after it has been adjusted to its proper position, and heads including the sides of the motor-casing, the pole-piece being entirely housed within the motor-yoke and said heads.

7. In an electric motor, the combination with a yoke, of a base-plate upon which said yoke is mounted, the said base-plate being provided with four guide-surfaces which insure a proper mounting of the yoke thereon, oblong openings in said base-plate, screws penetrating the base of the yoke and passing through said oblong openings, a bar below the base-plate to which said screws are connected, and a horizontal adjusting-screw mounted on the top of the base-plate and adapted to shift the motor-casing to adjust it to proper position, substantially as described.

697,985. MACHINE FOR SLITTING FABRIC. WILLIAM E. COCHRAN, Hyatt, and JAMES A. COCHRAN, Brooklyn, N. Y. Filed June 20, 1901. Serial No. 86,062. (No model.)

Claim.—1. In a machine for slitting a fabric into longitudinal strips, the supporting-table, the feed-roller 26, 27, for drawing the fabric through the machine, and a tension device for engaging and acting on the entire width of the fabric and maintaining a tension on that portion of

the fabric between it, said tension device, and said roller, a free space being provided beneath said portion of the fabric under tension, combined with the knife rigidly held in the path of said fabric intermediate said tension device and said rollers and adapted to engage and slit the fabric as the latter is moved forward against it; substantially as set forth.

2. In a machine for cutting a fabric into longitudinal widths, the supporting-table, the feed-rollers 26, 27, for drawing the fabric through the machine, and a tension device for engaging and acting upon the entire width of fabric and maintaining a tension on that portion of the fabric between it, said tension device, and said rollers, said fabric passing at an angle from said tension device to said rollers with a free space provided beneath the same, combined with a knife rigidly held in the path of said fabric and at an angle thereto intermediate said tension device and said rollers and adapted to engage and slit the fabric as the latter is moved forward against it; substantially as set forth.

3. In a machine for cutting a fabric into longitudinal widths, the supporting-table, the feed-rollers 26, 27, for drawing the fabric through the machine, and a tension device for engaging and acting upon the entire width of fabric and maintaining a tension on that portion of the fabric between it, said tension device, and said rollers, a free space being provided beneath said portion of the fabric under tension, combined with the knife rigidly held in the path of said fabric intermediate said tension device and said rollers and adapted to engage and slit the fabric as the latter is moved forward against it; the transverse bar 28 from which said knife is supported, and means for securing said knife in predetermined positions along said bar in accordance with the widths of fabric to be formed; substantially as set forth.

4. In a machine for cutting a fabric into longitudinal widths, the supporting-table, the feed-rollers 26, 27, for drawing the fabric through the machine, and a tension device for engaging and acting upon the entire width of fabric and maintaining a tension on that portion of the fabric between it, said tension device, and said rollers, a free space being provided beneath said portion of the fabric under tension, combined with the knife rigidly held in the path of said fabric intermediate said tension device and said rollers and adapted to engage and slit the fabric as the latter is moved forward against it, the roll to receive and wind up the severed width of fabric, the shaft upon which said roll is detachably mounted, means for rotating said shaft and roll, the swiveling bearing in which one end of said shaft is mounted, and a bearing for detachably holding the other end of said shaft; substantially as set forth.

5. In a machine for cutting a fabric into longitudinal widths, the tension device for acting on the fabric while the latter is fed through the machine, and the feed-rollers 26, 27, to which the fabric passes after leaving the said tension device, combined with the knife adapted to engage and slit the travelling fabric into widths, and the means for raising and permitting the lowering of said roller 27, said means comprising the wedge-bar below and adapted to engage said lever-arm, and the pivoted and laterally-movable frame for engaging and operating said wedge-bar; substantially as set forth.

has adapted to engage the shaft portions of the said roller; and the lever mechanism for operating said wedge-bar; substantially as set forth.

6. In a machine for cutting a fabric into longitudinal widths, the tension device for acting on the fabric while the latter is fed through the machine, and the feed-rollers 26, 27, to which the fabric passes after leaving the said tension device, combined with the knife adapted to engage and slit the travelling fabric into widths, and the means for elevating and permitting the lowering of said roller 27, said means comprising the lever-arm disposed below the ends of the shaft for said roller 27, the wedge-bar below and adapted to engage said lever-arm, and the pivoted and laterally-movable frame for engaging and operating said wedge-bar; substantially as set forth.

697,986. CONTROLLER FOR ELECTRIC VEHICLES. HENRY E. OUTLER, Chicago, Ill. Filed Aug. 24, 1906. Serial No. 736,364. (No model.)

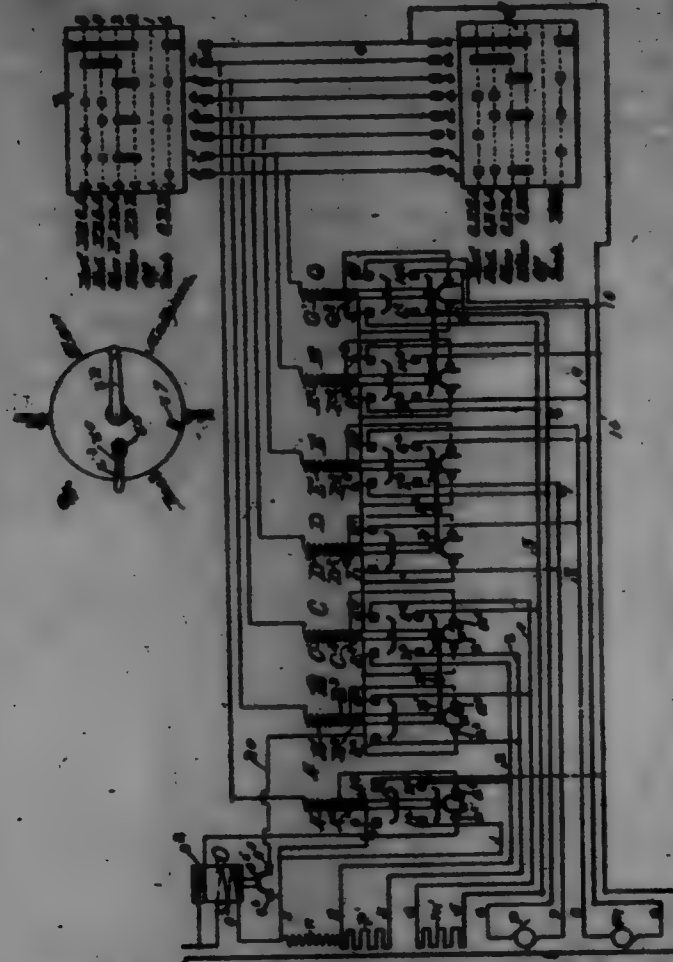

Claim.—1. In a controller, the combination with the several elements of the power-supply to be connected in varying relations, of contacts connected therewith, a plurality of solenoids for controlling the several contacts, a switching device for controlling said solenoids and a master-solenoid for controlling the circuit through said several solenoids, substantially as described.

2. In a controller, the combination with the several elements of the power-supply to be connected in varying relations, of contacts connected therewith, a plurality of solenoids for controlling the several contacts, a switching device for closing circuit through the solenoids as desired and a master-solenoid for decreasing the current through the working solenoids after the same have attracted their cores, substantially as described.

3. In a controller, the combination with the several elements of the power-supply to be connected in varying relations, of contacts connected therewith, a plurality of solenoids for opening and closing circuit through the several contacts, a controller-roller and brushes co-operating therewith to close circuit through the respective solenoids, a master-solenoid and a brush associated therewith and adapted to co-operate with the controller-roller to energize the master-solenoid and de-energize the current through the other solenoids, substantially as described.

4. In a controller, the combination with the several elements of the power-supply to be connected in varying relations, of contacts connected therewith, a plurality of solenoids for opening and closing circuit through the several contacts, a controller-roller and brushes co-operating therewith to close circuit through the respective solenoids, a master-solenoid, a brush connected therewith and contacts on the controller-roller arranged to engage said brush to close circuit through the master-solenoid while the controller is being moved from one position to another and to disengage said brush when the controller-roller occupies one of the positions of rest thereof, substantially as described.

697,987. CONTROLLER FOR ELECTRIC VEHICLES. Ernst H. Outler, Chicago, Ill. Filed Aug. 24, 1938. Serial No. 738,388. (No model.)

Claim.—1. In a controller for electric motors, the combination with the fields and the armatures of a pair of electric motors, of contacts arranged to connect the fields either in series or in parallel relation, contacts arranged to connect the armatures either in series or in parallel relation independently of said fields, a plurality of solenoids for controlling circuit through the several contacts, and a switching device for actuating the solenoids, substantially as described.

2. In a controller for electric motors, the combination with the field and the armatures of a pair of electric motors, of resistances associated with the armatures and the fields, contacts for controlling circuit through said resistances, contacts for connecting the fields in series or parallel, contacts for connecting the armatures in series or parallel independently of said fields, a plurality of solenoids for controlling said contacts, and a switching device for connecting the several solenoids in circuit as desired, substantially as described.

3. In a controller, the combination with a plurality of contacts, of a plurality of solenoids for controlling circuit therethrough, one end of each solenoid being connected with one side of the supply-circuit, a series of brushes one connected with the opposite end of each solenoid, and a contact-plate connected with the opposite side of the supply-circuit and having raised contact-surfaces arranged to engage the respective brushes to close circuit through the several solenoids, substantially as described.

4. In a controller, the combination with the several elements of the source of power supply to be connected in varying relations, of contacts connected therewith, a plurality of solenoids for controlling the circuits through the several contacts, and solenoids being provided with main and auxiliary windings, and a short-circuit normally provided across the auxiliary winding and adapted to be opened when the arc is attracted to thereby connect the auxiliary winding in circuit, substantially as described.

5. In a controller, the combination with the several elements of the source of power-supply to be connected in varying relation, of contacts connected therewith, a plurality of solenoids for controlling the circuits through the several contacts, and an over-ride solenoid for controlling the circuits through the solenoids, substantially as described.

3. In a controller, the combination with the several elements to be connected in varying relations of contacts connected therewith, a plurality of solenoids for controlling the circuits through the several contacts, and an overcoil-solenoid for controlling the circuits through the solenoids, and an overcoil-solenoid being provided with a series winding and a shunt-winding, and a solenoid for controlling the circuit through said shunt-winding, substantially as described.

7. In a controller for electric motors, the combination with a pair of electric motors, and a solenoid for connecting the fields thereof in parallel,

a solenoid for connecting said fields in series, a switching apparatus for closing circuit through the solenoids, and separate means for varying the circuit connection of the armatures of said motors, substantially as described.

3. In a controller for electric motors, the combination with a pair of electric motors, of a solenoid for connecting the fields thereof in parallel, of a solenoid for connecting said fields in series, a connection between the cores of said solenoids whereby but one of said cores can be attracted at a time, and overruling apparatus for closing circuits through the solenoids, substantially as described.

2. In a controller for electromotors, the combination with a pair of motors, of a colenoid for connecting the armatures thereof in series, a solenoid for connecting the armatures in parallel, switching apparatus for closing circuit through said solenoids, and separate means for varying the direct connections of the field of said motors, substantially as described.

10. In a controller for electric motors, the combination with a pair of motors of a solenoid for connecting the armature thereof in series, a solenoid for connecting the armature in parallel, a connection between the cores of said solenoids whereby but one of said cores can be attracted at a time, and switching apparatus for closing circuit through the solenoids, substantially as described.

11. In a controller for electric motors the combination with a pair of electric motors, of a solenoid for connecting the armatures thereof in circuit in one direction, a solenoid for connecting the said armatures in the reversed direction, switching apparatus for closing circuits through the solenoids, and separate means for varying the current arrangement of the field of said motors, substantially as described.

12. In a controller for electric motors, the combination with a pair of electric motors, of a solenoid for connecting the fields thereof in circuit in series, a solenoid for connecting said fields in parallel, switching apparatus for closing circuit through the solenoids, and separate means for varying the circuit arrangement of the armatures of said motors, substantially as described.

13. In a controller for electric motors, the combination with a pair of electric motors, of a solenoid for connecting the fields thereof in parallel, a solenoid for connecting the fields thereof in series, a solenoid for connecting the armatures thereof in parallel, a solenoid for connecting the armatures thereof in series, and switching apparatus for closing circuit through the several solenoids, substantially as described.

14. In a controller for electric motors, the combination with a pair of electric motors, of a solenoid for connecting the fields thereof in parallel, a solenoid for connecting the fields thereof in series, a solenoid for connecting the armatures in circuit in one direction, a solenoid for connecting the armatures in circuit in the opposite direction, and reversing apparatus for changing circuit through said several solenoids, substantially as described.

15. In a controller for electric motor, the combination with a pair of electric motor, of a solenoid for connecting the armature thereof in series, a solenoid for connecting said armatures in parallel, a resistance, a solenoid for connecting said resistance in closed circuit with said armature, and overrunning apparatus for closing circuit through said solenoid solenoids, substantially as described.

16. In a controller for electric motors, the combination with a pair of electric motors having stator fields, of a solenoid through said stator fields, a solenoid for controlling the crumsters in series, a solenoid for controlling the crumsters in parallel, a resistance, a solenoid for controlling the crumsters in series, and switching apparatus for closing circuit through the several solenoids, substantially as described.

697,988. FINISHING AND SHAPING METALLIC GOODS. LAM-
AND B. DAVIS, Erie, Pa. Filed May 2, 1900. Serial No. 715,204. (No
model.)

Claim.—1. A rolling mechanism comprising two opposed disks or rolls having their axes arranged in different planes $a' a'$ and $a'' a''$, respectively, and also in intersecting planes $a' a'$ and $a' a''$, the contact portions of the opposing faces of said disks or rolls converging toward their axes, the convergences and the shape of said opposing faces being such that the decreasing diameter of the billet between them compensates for the decreasing speed of said faces toward the axes of the disks or rolls, whereby every point in the surface of the billet has the same speed of rotation about the axis of the billet and twisting of the billet by the action of said contact-faces is wholly avoided.

2. A rolling mechanism comprising two opposed disks or rolls having their axes arranged in different planes σ' and σ'' , respectively, and also in intersecting planes σ' and σ'' , the contact portions of the opposing faces of said disks or rolls converging toward their axes, the convergence and the shape of said opposing faces being such that the decreasing diameter of the fillet between them compensates for the decrease

ing speed of said flange toward the axis of the disks or cone, whereby every point in the surface of the billet has the same speed of rotation about the axis of the billet and twisting of the billet by the action of said contact-flange is wholly avoided, and a mandrel located in the line of the pass and between the contacting flange of the disks.

3. A rolling mechanism comprising two opposed disks or rolls having their axes arranged in different planes $s's'$ and $s''s''$, respectively, and also in intersecting planes $s's'$ and $s''s''$, the contact portions of the opposing faces of said disks or rolls converging toward their axes, the convergences and the shape of said opposing faces being such that the decreasing diameter of the billet between them compensates for the decreasing size of said faces toward the axes of the disks or rolls, whereby every point in the surface of the billet has the same speed of rotation about the axes of the billet and twisting of the billet by the action of said contact-faces is wholly avoided, said contact-faces rotating in opposite directions toward said axes, whereby the direction of the pass is from the outer contacting portions of the disk toward said axes.

4. A rolling mechanism comprising two opposed disks or rolls having their axes arranged in different planes s and s' , respectively, and also in intersecting planes σ and σ' , the contact portions of said disks or rolls converging toward their axis, the convergences and the shape of said opposing faces being such that the decreasing diameter of the billet between them compensates for the decreasing speed of said faces toward the axis of the disks or rolls, whereby every point in the surface of the billet has the same speed of rotation about the axis of the billet and twisting of the billet by the action of said contact-faces is wholly avoided, said contact-faces rotating in opposite directions toward said axis, whereby the direction of the pass is from the outer contacting portions of the disks toward said axis, and a mandrel located in the line of the pass and between the contacting faces of the disks and pointing away from the axis of the rolls.

8. A rolling mandrel comprising two opposing discs or rolls having their axes arranged in different planes $\alpha \alpha'$ and $\alpha \alpha'$, respectively, and also intersecting planes $\sigma \sigma'$ and $\sigma \sigma'$, the contacting portions of said discs or rolls converging toward the axes, the convergence and the shape of said opposing faces being such that the diametrical diameter of the billet between these components for the decreasing speed of said discs toward the axes of the discs or rolls, whereby every point in the surface of the billet has the same speed of rotation about the axis of the billet and twisting of the billet by the action of said contact faces is wholly avoided, said contact faces rotating in opposite directions toward said axes, whereby the direction of the pass is from the outer contacting portions of the discs toward said axes, said discs also provided with the spreading faces $\beta \beta'$ leading from the narrowest point in the pass toward the center of the discs, in combination with an enlarging mandrel located in the pass between the surfaces $\beta \beta'$ and pointing away from the axes of the rolls.

697,989. TELEPHONE-EXCHANGE SYSTEM. WILLIAM M. DAVIS, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Dec. 7, 1922. Serial No. 22,905. (No model.)

Class.—1. In a telephone-exchange system, the combination with a telephone-line extending from a subscriber's station to an exchange, of a line-indicator at the exchange provided with signal-revealing means, means whereby the said line-indicator may be operated to effect a signal, restoring means for restoring the signal-revealing means, means controlled by the signal-revealing means for governing the operation of the restoring means in part, and a combining appliance for connecting the said tele-

phone-line in telephonic communication with another telephone circuit, said switching appliance serving in conjunction with the signal-receiving means to jointly control the operation of the restoring means, substantially as described.

2. The combination with a telephone-line extending from a subscriber's station to an exchange, of a line-indicator having signal-revealing means, means whereby the subscriber may effect the operation of the signal-revealing means, an electromagnet provided with an armature adapted for engagement with the signal-revealing means when the latter is actuated to reveal a signal, a retarding-circuit including the electromagnet provided with two openings, means whereby the signal-revealing means, when actuated, may close one of the said openings, and a switching appliance for connecting the said telephone-line with another telephone-circuit adapted also to close the second opening in the retarding-circuit to return the signal-revealing means, substantially as described.

3. In a telephone-exchange system, the combination with subscribers' telephone-lines extending from subscribers' stations to an exchange, of switching apparatus at the exchange for connecting the said lines, a clearing-out indicator having signal-revealing means connected in the circuit between the subscribers' stations, means for restoring the signal-revealing means, means governed by the signal-revealing means for partially controlling the operation of the restoring means, and means governed by the said switching apparatus acting in co-operation with the means governed by the signal-revealing means to jointly control the operation of the restoring means, substantially as described.

4. In a telephone-exchange system, the combination with subscribers' telephone-lines extending from subscribers' stations to an exchange, of switching apparatus at the exchange for connecting the said lines, a clearing-out indicator having signal-revealing means connected in circuit between the subscribers' stations, an electromagnet provided with an armature adapted for engagement with the signal-revealing means when the latter is operated to reveal a signal, a restoring-screw provided with two openings, means whereby the signal-revealing means when actuated may close one of the said openings, and means governed by the said switching apparatus for closing the remaining opening in the restoring-screw substantially as described.

5. In a telephone-exchange system, the combination with subscribers' telephone-lines extending from subscribers' stations to an exchange, of switching apparatus having a connecting-plug at the exchange for connecting the said lines, a clearing-out indicator having signal-revealing means connected in circuit between the subscribers' stations, an electromagnet provided with an armature adapted to restore the signal-revealing means after the latter is operated to reveal a signal, a restoring-circuit provided with two openings, means whereby the signal-revealing means when actuated may close one of the said openings, and a plug-coat switch operated by the plug when acted to close the remaining opening in the restoring-circuit, substantially as described.

6. In a telephone-exchange system, the combination with subscriber

telephone-line connected for conversation, of an indicator included in series in the telephone circuit, a condenser in shunt of the winding of the indicator, and a magnet-generator at a subscriber's station for propagating signaling-currents, the generator serving to charge the condenser which, upon discharge, serves to operate the indicator, substantially as described.

7. In a telephone-exchange system, the combination with telephone-line, of a switching apparatus for connecting the same for conversation, a clearing-out indicator associated with the telephone-line by the said switching apparatus and included in series with the telephone circuit between the subscriber's station, a magnet-generator at a subscriber's station, and a condenser in shunt of the clearing-out indicator, the generator serving to charge the condenser which, upon discharge, serves to operate the indicator, substantially as described.

8. In a telephone-exchange system, the combination with subscriber/telephone-line connected for conversation, of an indicator, a condenser in shunt of the winding of the indicator, and a magnet-generator at a subscriber's station for propagating signaling-currents, said magnet-generator serving to charge the condenser, which, upon discharge, is adapted to effect the operation of the indicator, substantially as described.

697,990. CLEARING-OUT SIGNALING APPARATUS. WILLIAM H. DAVE, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Jan. 11, 1901. Serial No. 49,514. (No model.)

Claim.—1. In a telephone-exchange system, the combination with a telephone-line extending from a subscriber's telephone-station to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, an indicator having its operating electromagnet included in circuit with the said telephone-line and circuitally in a cord-circuit, a source of current, a telephone switch-hook at the subscriber's station adapted when relieved of the influence of the telephone-receiver to close circuit through said battery and magnet of the indicator to correspondingly operate the indicator, and a switch with suitable connections, operated by the electromagnet from its series connection with the cord-circuit and maintaining said magnet in circuit with the said source of current, whereby the signal may be maintained in the condition to which it has been brought while the electromagnet controlling the same is removed from the path of voice-currents, the telephone switch-hook at the subscriber's station, when actuated through the influence of the restored receiver, serving to open the circuit through the electromagnet of the indicator to restore the indicator, substantially as described.

2. In a telephone-exchange system, the combination with a telephone-line extending from a subscriber's telephone-station to an exchange, of cord-connecting apparatus at the exchange, an indicator having its operating-electromagnet included in circuit with the said telephone-line and circuitally in a condenser forming a part of the telephone-circuit, a source of

current, a telephone switch-hook at the subscriber's station adapted when relieved of the influence of the telephone-receiver to close circuit through said battery and magnet of the indicator to correspondingly operate the indicator, and a switch with suitable connections, operated by the electromagnet when thus included in circuit, serving to short the electromagnet from the telephone circuit and maintain the said magnet in circuit with said source of current, whereby the signal may be maintained in the condition to which it has been brought, while the electromagnet controlling the same is removed from the path of voice-currents, the telephone switch-hook at the subscriber's station, when actuated through the influence of the restored receiver, serving to open the circuit through the electromagnet of the indicator to restore the indicator, substantially as described.

3. In a telephone-exchange system, the combination with telephone-line extending from subscriber's stations to an exchange, of cord-connecting apparatus at the exchange, indicators at the exchange having their electromagnets circuitally included serially in the cord-circuit, one of the said indicators being connected with the calling subscriber and the other with the called subscriber, a telephone switch-hook at each subscriber's station adapted to close circuit through the magnet of the indicator connected therewith, and a switch with its connections operated by the called subscriber's indicator-magnet for charging the said magnet from the cord-circuit and maintaining them in closed circuit, whereby the signal may be maintained in the condition in which they have been placed, substantially as described.

4. In a telephone-exchange system, the combination with telephone-line extending from subscriber's stations to an exchange, of cord-connecting apparatus at the exchange, indicators at the exchange having their electromagnets circuitally included serially in the cord-circuit, one of the said indicators being connected with the calling subscriber and the other with the called subscriber, a bridge connection between the sides of said telephone-line including a source of current, a telephone switch-hook at each subscriber's station adapted to close circuit through the magnet of the indicator connected therewith and the said source of current, and a switch with its connections operated by the called subscriber's indicator-magnet for charging the said magnet from the cord-circuit and including them in parallel relation with each other in the same bridge with the source of current, whereby the signal may be maintained in the condition in which they have been placed, substantially as described.

5. In a telephone-exchange system, the combination with telephone-line extending from subscriber's stations to an exchange, of cord-connecting apparatus at the exchange, indicators at the exchange having their electromagnets circuitally included serially in a cord-circuit, one of the said indicators being connected with the calling subscriber and the other with the called subscriber, a bridge connection between the sides of said telephone-line including a source of current, the said bridge connection being joined with the normal cord conductor between the said electromagnets, a telephone switch-hook at each subscriber's station adapted to close circuit through the magnet of the indicator connected therewith and the said source of current, and a switch with its connections operated by the called subscriber's indicator-magnet for charging the said magnet from the cord-circuit and including them in parallel relation with each other in the same bridge with the source of current, whereby the signal may be maintained in the condition in which they have been placed, substantially as described.

6. In a telephone-exchange system, the combination with telephone-line extending from subscriber's telephone-stations to an exchange, of indicators at the exchange having their electromagnets included serially in the telephone-line uniting the subscribers, one of the said indicators being connected with the calling subscriber and the other with the called subscriber, a telephone switch-hook at each subscriber's station adapted to close circuit through the magnet of the indicator connected therewith, and a switch with its connections operated by the called subscriber's indicator-magnet for charging the said magnet from the telephone circuit and maintaining them in closed circuit, whereby the signal may be maintained in the condition in which they have been placed, substantially as described.

7. In a telephone-exchange system, the combination with telephone-line extending from subscriber's stations to an exchange, of indicators at the exchange having their electromagnets included serially in the telephone circuit between the subscribers, one of the said indicators being connected with the calling subscriber and the other with the called subscriber, a bridge connection between the sides of said telephone-line including a source of current, a telephone switch-hook at each subscriber's station adapted to close circuit through the magnet of the indicator connected therewith and the said source of current, and a switch with its connections operated by the called subscriber's indicator-magnet for charging the said magnet from the telephone circuit and including them in the same bridge with the source of current, whereby the signal may be maintained in the condition in which they have been placed, substantially as described.

8. In a telephone-exchange system, the combination with telephone-line extending from subscriber's stations to an exchange, of indicators at the exchange having their electromagnets included serially in a side of the telephone circuit between the subscriber's station, one of the said indicators being connected with the calling subscriber and the other with the called subscriber, a bridge connection between the sides of said telephone-line including a source of current, the said bridge connection being joined with the side of the telephone circuit containing the said electromagnets and between the said electromagnets, a telephone switch-hook at each subscriber's station adapted to close circuit through the magnet of the indicator corresponding thereto and the said source of current, and a switch with its connections operated by the called subscriber's indicator-magnet for charging the said magnet from the telephone-circuit and including them in parallel relation with each other in the same bridge with the source of current, whereby the signal may be maintained in the condition in which they have been placed, substantially as described.

697,991. IMPROVED OVERHEAD TELEPHONE-EXCHANGE SYSTEM. WILLIAM H. DAVE, Chicago, Ill., assignor to Stromberg-Carlson Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed June 17, 1901. Serial No. 49,599. (No model.)

Claim.—1. In a multiple-overhead-telephone-exchange system, the combination with telephone-line extending from subscriber's stations to the line-jacks upon the different boards or sections of a multiple switch-board, of test-thimbles for the said jacks, cord-connecting apparatus at each board or section of the exchange, including a connecting-peg for connecting a calling with a called subscriber, a switch provided with a normal and an alternate contact, a testing-conductor terminating in the normal contact, a test-indicator in circuit with the test-conductor, a test-battery connected at the remaining terminal of the said test-conductor with the alternate contact condition, the terminal of the answering end of the tip-circuit, a connection between the remaining terminal of the test-battery and the above-ends of the cord-circuit, whereby the test-indicator may be connected with the said remaining terminal of the test-battery and circuit through the testing appliance completed upon the application of the connecting-peg to a test-thimble of a busy line, a relay in the conductor extending between the test-battery and the above of the connecting and testing peg, and means controlled by the connecting-peg and the called-subscriber's jack for clearing circuit through the said relay, whereby the said relay may be thrown from its normal test-contact to the alternate contact that is a terminal of the answering-connection of the tip-circuit, whereby the cord-circuit is completed, substantially as described.

2. In a multiple-overhead-telephone-exchange system, the combination with telephone-line extending from subscriber's stations to the line-jacks upon the different boards or sections of a multiple switch-board, of test-thimbles for said jacks, cord-connecting apparatus at each board or section of the exchange, including a connecting-peg for connecting a

calling with a called subscriber, a switch provided with a normal and an alternate contact, a testing-conductor terminating in the normal contact, a test-indicator in circuit with the test-conductor, a test-battery connected at the remaining terminal of the said test-conductor with the alternate contact condition, the terminal of the answering end of the tip-circuit, a connection between the remaining terminal of the test-battery and the above-ends of the cord-circuit whereby the test-indicator may be connected with the said remaining terminal of the test-battery and circuit through the testing appliance completed upon the application of the connecting-peg to a test-thimble of a busy line, and a relay in the conductor extending between the test-battery and the above of the connecting and testing peg, the called-subscriber's telephone-line, in cooperation with its spring-jack and the connecting-peg inserted therein, serving to complete circuit through the relay to disconnect the terminal of the connecting or testing peg portion of the tip-circuit and to complete the cord-circuit, substantially as described.

697,992. TELEPHONE-EXCHANGE SYSTEM. WILLIAM H. DAVE, Chicago, Ill., assignor to Stromberg-Carlson Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 8, 1901. Serial No. 70,555. (No model.)

Claim.—1. The combination with telephone-line extending from subscriber's stations to an exchange, of a cord-circuit at the exchange, electromagnets included serially in the cord-circuit, a source of current in circuit with the telephone-line, a bridge connection across the telephone-circuit and in circuit with the said source of current and connected between the windings of the said electromagnets, whereby each electromagnet may be controlled by the corresponding telephone-station independently of the other, the armatures of the said electromagnets being provided with contacts that are engaged by the armatures when said electromagnets are energized, supplemental electromagnets included independently of each other in energizing-circuits, these energizing-circuits including each the armature and contact of the first aforesaid electromagnet, the armatures of the supplemental electromagnets being provided with springs to effect their retraction when the said supplemental electromagnets are deenergized, contacts for the latter armatures engaged thereby when retracted, supervisory signals and circuits for the same including the armatures and contacts of the supplemental electromagnets, substantially as described.

2. The combination with telephone-line extending from subscriber's stations to an exchange, of a cord-circuit at the exchange, electromagnets included serially in the cord-circuit, a source of current in circuit with the telephone-line, a bridge connection across the telephone-circuit and in circuit with the said source of current and connected between the windings of the said electromagnets, whereby each electromagnet may be controlled by the corresponding telephone-station independently of the other, the armatures of the said electromagnets being provided with contacts that are engaged by the armatures when said electromagnets are energized, supplemental electromagnets included independently of each other in energizing-

circuits, these energizing-circuits including each the armature and contact of the first solenoid electromagnet, the armatures of the supplemental electromagnets being provided with springs to effect their retraction when the said supplemental electromagnets are deenergized, contacts for the latter armatures engaged thereby when retracted, supervisory signals and circuits for the same, including the armatures and contacts of the supplemental electromagnets, the circuits including the supervisory or clearing-out indicators being formed in part by the portion of the cord-circuit and line-springs of the spring-jacks, whereby the said supervisory signals are restored or rendered inert when the cord-circuit is disconnected from the telephone lines, substantially as described.

3. The combination with telephone-lines extending from substations to an exchange, of a cord-circuit at the exchange for uniting the telephone-lines, an electromagnet included in the cord-circuit, a contact engaged by the armature of the electromagnet when the said armature is attracted, a supplemental electromagnet included in an energizing-circuit which contains the armature and the contact of the solenoid electromagnet, the armature of the supplemental electromagnet being provided with a spring for retracting the same when the said supplemental magnet is deenergized, a contact engaged by the armature of the supplemental magnet when retracted, a clearing out signal included in a circuit which contains the armature and contact of the supplemental electromagnet, the clearing-out-indicator circuit being composed in part by a portion of the cord-circuit, and a line-spring in circuit therewith, whereby upon a disconnection of the cord-circuit the clearing-out signal is restored or rendered inert, substantially as described.

697,998. TELEPHONE-EXCHANGE SYSTEM. WILLIAM M. DAVE, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Aug. 16, 1901. Serial No. 72,264. (No model.)

Claim.—1. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser directly in shunt of each supervisory magnet, and a source of current in circuit with the said bridge, substantially as described.

2. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser in shunt of each supervisory magnet, and a source of current in the said bridge, substantially as described.

3. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at

the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser directly in shunt of each supervisory magnet, and a source of current in circuit with the said bridge, the said electromagnets being included in the same side of the combined circuit, substantially as described.

4. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser directly in shunt of each supervisory magnet, and a source of current in the said bridge, the said electromagnets being included in the same side of the combined circuit, substantially as described.

5. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser directly in shunt of each supervisory magnet, a source of current in circuit with the said bridge, and an impedance in the said bridge, substantially as described.

6. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser directly in shunt of each supervisory magnet, a source of current in the said bridge, and an impedance in the said bridge, substantially as described.

7. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser directly in shunt of each supervisory magnet, a source of current in circuit with the said bridge, the said electromagnets being included in the same side of the combined circuit, and an impedance in the said bridge, substantially as described.

8. In a telephone system, the combination with telephone-lines extending from substations to an exchange, of cord-connecting apparatus at the exchange for uniting subscribers for conversation, a bridge placing the telephone-lines when connected in short-circuit relation, two supervisory signals, each of said telephone-circuits including the operating-magnet of a supervisory signal, a condenser directly in shunt of each supervisory magnet, a source of current in the said bridge, the said electromagnets being included in the same side of the combined circuit, and an impedance in the said bridge, substantially as described.

9. Cord-connecting apparatus, comprising the two strands of a cord-circuit, a bridge, two supervisory relays, one included on each side of said bridge, and a condenser directly in shunt of each relay-winding, substantially as described.

697,994. PROCESS OF MAKING THYMOL. MARCEL DUBOIS, Paris, France. Filed July 20, 1901. Serial No. 69,267. (No specification.)

Claim.—1. A process for the manufacture of para-cymene-3-sulfonic acid, which consists in heating during several hours in a digester, at a temperature between 100° centigrade and 170° centigrade, a mixture of 2-bromo-para-cymene 3 or 5 sulfonic acid with ammonia and powdered zinc, substantially as described.

2. The process of manufacturing thymol which consists in making with alkaline hydrazide at temperatures bordering on 300° centigrade para-cymene-3-sulfonic acid, obtained by heating for several hours at a temperature between 100° centigrade and 170° centigrade, a mixture of 2-bromo-para-cymene sulfonic acid with ammonia and powdered zinc, substantially as described.

697,995. WATER-GASE. JOHANN DORN, Szilak-on-the-Pyren, Austria-Hungary. Filed Mar. 16, 1901. Serial No. 51,504. (No model.)

Claim.—1. In combination with a steam-blower, a tube or casing mounted therewith supporting a gas-glass, said casing having openings to said glass and to the outside air, and a movable plug located in said casing and having openings adapted respectively to place the interior of the boiler in communication with said tube or with the outside air and a fixed tube within the boiler having one end extending above the water-level and the other in line with the bore of said plug, substantially as described.

2. In combination with a steam-baker, a tube or casing connected therewith supporting a gage-glass, said casing having openings to said glass and to the outside air, a plug located in said casing and having transverse openings a stationary tube within the boiler having one end extending above the water-level and the other end in line with the lower end of said tubular plug, and a suitable handle whereby said plug may be rotated and also moved longitudinally to cause its lower end to abut against the stationary tube, substantially as described.

697,996. LUBRICANT AND PROCESS OF MAKING SAME.
WILLIAM F. BOWEN, Jersey City, N. J. Filed Sept. 20, 1904. Serial No. 77,164. (No specimens.)

Claim.—1. As a new article of manufacture, a lubricant consisting of particles of a solid lubricant coated with an oil in which it is insoluble and suspended in an enveloping oil with which the coating-oil is not miscible.

2. As a new article of manufacture, a lubricant consisting of particles of graphite coated with oil and suspended in an enveloping oil with which the coating-oil is not miscible.

3. As a new article of manufacture, a lubricant consisting of particles of graphite coated with ester-oil, suspended in an enveloping oil with which the ester-oil is not miscible.

4. The process of manufacturing a lubricant consisting of coating particles of a solid lubricant with an oil in which it is not soluble and subsequently placing the particles so coated in an oil with which the coating-oil is not miscible.

5. The process of manufacturing a lubricant consisting of coating particles of graphite with oil and subsequently placing the particles so coated in an oil with which the coating-oil is not miscible.

6. The process of manufacturing a lubricant consisting of coating particles of graphite with ester-oil and subsequently placing the coated particles in an oil with which the ester-oil is not miscible.

697,997. MACHINES FOR CUTTING PICTURE-MATS. PHILIP BARKER, Detroit, Mich. Filed July 12, 1904. Serial No. 67,967. (No model.)

Claim.—1. A machine of the character described, comprising a guide-block in fixed relation to the work-table, guide-grooves formed in said block, intersecting each other at right angles, slides traveling in said grooves, a bar pivotally supported on one of said slides and extending on opposite sides of said block, a slot formed in one arm of said bar, an indicator-slide secured on said arm and connected with the other slide through said slot, means for adjusting said slide in relation to the other slide and a cutter adjustably mounted on the opposite end of said bar, substantially as described.

2. In a machine of the character described, the combination with a work-table, of a guide-block detachably secured thereon, intersecting guide-grooves formed in the top of said block and slides traveling in said grooves, a cross-bar having a slight lateral bend pivotally connected with said slides, means for adjusting one of said slides in relation to the other, a knife-holder slidably secured on the opposite end of said bar, and a vertically-adjustable traveling knife or cutter pivoted in said knife-holder, substantially as described.

3. In a machine of the character described, the combination with the work-table, of an apertured plate let into the table, a vertical centering-pin, a guide-block having pins registering with said apertures, guide-grooves intersecting each other at right angles cut into the top of said block, slides fitting in said grooves, a bar extending across said block and having a laterally-bent portion, said bar being pivotally secured to one of said slides, a longitudinal slot formed in the short arm of said bar, an indicator-slide traveling on said arm, a pin connecting said indicator-slide with the other slide, an adjustable screw loosely pivoted in the outer end of said arm having a screw-thread engagement with said indicator-slide to adjust the slides in relation to each other and a trailing cutter pivoted in a bracket slidably secured upon the long arm of said bar.

4. In a machine for providing picture-mats with elliptical openings, the combination with the cutter-bearing bar having graduations marked thereon, a knife and knife-holder carrying a graduated stop slidably mounted on said bar, whereby one set of graduations may be used for the various thicknesses of mats and suitable means for guiding the knife in the operation of the machine to cause an elliptical or circular cut to be made in the mat-board, all arranged and operating substantially as described.

5. In a machine of the character described, the combination with a work-table, of a guide-block detachably secured thereon, guides intersecting each other at right angles formed on said block, slides traveling in said guides, a bar extending across said block and pivotally connected with one of said slides, a knife-holder slidably secured on one end of said bar and carrying a graduated stop registering with graduations formed on said bar, a slot and graduations formed in the opposite end of said bar, an indicator registering with said graduations and connected with the other one of said slides and means for adjusting said indicator and slide in relation to the other slide.

6. In a machine of the character described, the combination with a guide-block and slides traveling in grooves formed in said block and intersecting each other at right angles, of a bar having a slight lateral bend extending across said block and pivotally secured to one of said slides, a trailing knife and knife-holder adjustably secured on one end of said bar, and an indicator pivotally connected with the other slide, secured on the other end of said bar and means for adjusting the same, the pivot-pin of the slides and the chuck of the traveling knife all being in the same vertical plane, while the cutting-point of the knife is in a plane in rear thereof.

7. In a machine of the character described, a central guide-block having intersecting guide-grooves and slides traveling therein, of a cross-bar pivotally connected with said slides and projecting on opposite sides of the block, a pivoted knife and knife-holder adjustably mounted on one end of said bar and an elongated slot formed in the other end of said bar, an indicator slidably secured on said bar and connected through said slot with one of said slides and an adjusting-screw pivoted in the end of said bar and having a screw-thread engagement with said indicator to adjust the slides in relation to each other.

697,998. MEANS FOR ADJUSTING DYANOS OR MOTORS ON THEIR BED-PLATE. FREDERICK R. DUNNAN, Akron, Ohio. Filed Feb. 24, 1905. Serial No. 68,120. (No model.)

Claim.—1. An improved bed-plate for dynamos and motors having slots dipping from below, bolts with pyramidal heads to retain the dynamos or motors, substantially as shown and for the purpose specified.

2. The combination with a bed-plate for dynamos and motors, having slots with sides dipping outward from above, of bolts for retaining a dynamo or motor thereon having heads adapted to fit the sides of said slots, substantially as shown and described.

697,999. SIGNALING MECHANISM. ARTHUR F. DUNNAN, Boston, Mass. Filed May 21, 1904. Serial No. 68,494. (No model.)

Claim.—1. A portable signaling device comprising a case, a battery therein, a signal supported by said case, an electric circuit connecting said battery and signal, mechanism supported by said case for rendering said circuit effective at regular intervals and for rendering said circuit effective a plurality of times in succession at regular intervals, and device sup-

ported by said case and under the control of the operator for adjusting said mechanism, substantially as described.

2. In a signaling mechanism the combination of a signal, an electric circuit for controlling the operation of said signal, a series of brushes, a contact engaging one of said brushes at intervals, a series of contacts successively engaging another of said brushes at intervals, and means for bringing either of said brushes and the corresponding contacts in circuit, substantially as described.

3. In a signaling mechanism the combination of a signal, an electric circuit for controlling the operation of said signal, a series of brushes, an insulating drum, a contact-plate curved thereby and in said circuit, a projection on said plate arranged to engage one of said brushes, a series of projections on said plate arranged to engage another of said brushes, means for rotating said drum, and a switch for bringing either of said brushes in circuit, substantially as described.

4. In a signaling mechanism the combination of a signal, an electric circuit for controlling the operation of said signal, a series of brushes I, F, P, a switch for bringing any one of said brushes in circuit, an insulating drum K, a contact arranged to engage brush I, and contacts arranged to engage brush F, and a motor for rotating drum K, substantially as described.

698,000. **SLIDING ALARM HORN.** ALBION H. FINE, Hiale, N. Y. Filed Jan. 28, 1902. Serial No. 91,619. (No model.)

Claim.—In a sleigh, runabout, cart and loader, means connecting the runners with the seat-rails, the intermediate means being perpendicular and the outer means oppositely inclined, cross-bars connecting the several runners, means between the runners, runners and cross-bars, side bars clipped to the seat-rails, side springs supported by the side bars, a rear spring attached to the side springs, a rod or bar connecting the front ends of the side springs, a sledge-body supported upon the rear spring and front bar connecting the side springs, shafts, and means connecting the cross-bar of the shafts with the front cross-bar joining the runners, substantially as set forth.

698,001. **IMPROVED ATTACHMENT FOR HORN.** BENJAMIN F. FINE, ALBION, N. Y. Filed May 6, 1901. Serial No. 91,620. (No model.)

Claim.—The herein-described device, consisting of a rod adapted to be engaged by a horn and having a split end and to form jaws to receive and retain the shank of a bell, a sleeve having a tapering channel fitting upon said rod near its split end, cross-threads upon the rod below the sleeve, and a nut upon the cross-threads adapted to contract the lower end of the sleeve to form the sleeve around to compress the split end of the rod upon the shank of the bell.

698,002. **IMPROVED ATTACHMENT FOR HORN.** BENJAMIN F. FINE, ALBION, N. Y. Filed Aug. 21, 1901. Serial No. 91,621. (No model.)

Claim.—1. The combination in a corner-fixture of a projecting post-piece having a plain flat face and a rib or shoulder projecting therefrom in position to engage the side of the rail part and having a beveled projection located in or on said plain face and a rail part having a plain flat face to engage the face of the rib part and a recess to receive the said projection and shoulder to engage the head of the projection and also adapted at the side or edge of its flat face to engage with the rib or shoulder of the post-piece, substantially as set forth.

2. The combination in a corner-fixture of a post-piece having a flat face, a beveled projection projecting from said flat face, a rail part having a flat face to engage the face of the post-piece, a recess to receive the projection and shoulder to engage the head of the projection and a rib or projection at the side of the flat face of the post-piece to engage the side of the rail or frame part, substantially as set forth.

698,003. **TURN OR RAG FRAME CATCH.** ALBION F. FINE, ALBION, N. Y. Filed May 6, 1901. Serial No. 91,622. (No model.)

Claim.—1. In a frame or bag frame, the combination, with a pair of frame-sections, of a holding-rod on one of said frame-sections, and a holding-projection or notch on the other of said frame-sections, said holding-rod comprising a cup-shaped plate, a finger-piece on said plate, a marginal projection on said plate with which said notch is adapted to be brought in holding engagement, a downwardly-projecting member on said holding-rod, extending through an opening in said frame-section, said downwardly-projecting member having a cut-away part 17, a holding-leg on said downwardly-projecting member, bent at a right angle thereto, or approximately so, a spring secured to said frame-section, an arm 11 on said spring having its free end extending into said cut-away part 17, and a spring-tenon 10 in engagement with said leg, and a downwardly-projecting extension on said marginal projection, said extension having a hook-shaped portion extending beneath a part of one of said frame-sections to limit the pivotal movement of said catch, substantially as and for the purposes set forth.

2. In a frame or bag frame, the combination, with a frame-section having a dotted part, of a holding-rod provided with a means of pivotal connection extending through the said dotted part, said downwardly-projecting member having a cut-away part 17, a holding-leg on said downwardly-projecting member, bent at a right angle thereto, or approximately so, a spring secured to said frame-section, a short arm 11 on said spring having its free end extending into said cut-away part 17, a spring-tenon 10 in engagement with the said leg, and a downwardly-projecting extension on said holding-rod having a hook-shaped portion extending beneath a part of one of said frame-sections to limit the pivotal movement of said catch, substantially as and for the purposes set forth.

3. In a frame or bag frame, the combination, with a frame-section having a dotted part, of a holding-rod provided with a means of pivotal connection extending through the said dotted part, a spring secured at one end to the lower portion of said frame-section, an arm 11 on said spring having its free end in engagement with said means of pivotal connection for the oscillation of said holding-rod, a spring-tenon 10 also in engagement with a portion of said means of pivotal connection of the said holding-rod, said a downwardly-projecting extension on said marginal projection, said extension having a hook-shaped portion extending beneath a part of one of said frame-sections to limit the pivotal movement of said catch, substantially as and for the purposes set forth.

4. The herein-described holding-rod for a frame or bag frame, comprising, a cup-shaped plate 12, a finger-piece on said plate, a downwardly-projecting holding member 16 on said cup-shaped plate, an inwardly-extending leg 18 on said member 16, and means on said plate 12 arranged to extend beneath the frame-section to limit the pivotal movement of the catch when in position upon the frame-section, substantially as and for the purposes set forth.

5. The herein-described holding-rod for a frame or bag frame, comprising, a cup-shaped plate 12, a finger-piece on said plate, a downwardly-projecting holding member 16 on said cup-shaped plate, an inwardly-extending leg 18 on said member 16, and a downwardly-projecting extension on said plate 12 having a hook-shaped portion extending beneath a part of the frame-section to limit the pivotal movement of the catch when in position upon the frame-section, substantially as and for the purposes set forth.

698,004. **SHED-PLASTER.** THOMAS J. GAYNE, Indianapolis, Ind., assignor of one-half to THOMAS F. GAYNE and WM. L. LIGHTFOOT, Indianapolis, Ind. Filed July 24, 1901. Serial No. 91,623. (No model.)

Claim.—1. In a shed-plaster, the combination with a dropping mechanism, of a belt provided with means for intermittently operating said dropping mechanism, a wheel rolling upon the ground, driving means between said wheel and belt, means for disconnecting said belt from the driving-wheel, and means for advancing said belt independent of its driving-wheel without disconnecting said belt from the driving-wheel.

2. In a shed-plaster, the combination with the main frame, supporting-wheel, and the axle thereof, of a counter-shaft, operable driving connection between said counter-shaft and axle, means for separating said connection, a rock-shaft forming part of a dropping mechanism, a belt driven by the counter-shaft, means carried by said belt for intermittently engaging and operating the rock-shaft, and means for rotating the counter-shaft independent of the axle without disconnecting the counter-shaft from the axle.

3. In a shed-plaster, the combination with the main frame, supporting-wheel and the axle thereof, of a counter-shaft, operable driving connection between said counter-shaft and axle, means for separating said connection, a rock-shaft forming part of a dropping mechanism, means for adjusting the counter-shaft toward and from the rock-shaft, a belt driven by the counter-shaft, means carried by said belt for intermittently engaging and operating the rock-shaft, and means for rotating the counter-shaft independent of the axle.

4. In a shed-plaster, the combination with a main frame, supporting-wheel, and axle, of a counter-shaft, a wheel mounted upon said counter-shaft and carrying a clutch member, a belt passing over said wheel and the axle, a clutch member applied upon the counter-shaft and normally held in engagement with the other clutch member, a belt driven by said counter-shaft, dropping mechanism, means carried by said belt for intermittently operating the dropping mechanism, a hand-shaft, and a driving connection between said hand-shaft and counter-shaft, substantially as and for the purposes set forth.

5. In a shed-plaster, the combination with a dropping mechanism, of a wheel rolling on the ground, driving connection between said wheel and dropping mechanism, means for disconnecting said connection between the wheel and dropping mechanism, and means for advancing said connection independent of the wheel but without disconnecting the driving connection.

698,005. **APPAREL-BELT.** WILLIAM SHANNON, New York, N. Y., assignor to S. Schaefer & Son, New York, N. Y., a Firm. Filed Jan. 9, 1902. Serial No. 91,624. (No model.)

Claim.—An apparel-belt provided at each end with a series of parallel transverse slots, removable tongues interwoven through said slots and having enlarged rear ends, and means for connecting the front ends of the tongues, substantially as specified.

698,006. **LAST-MAKING MACHINE.** EDWARD W. GUNN, Lynn, Mass., assignor of one-half to THOMAS W. GUNN, Lynn, Mass. Filed May 14, 1901. Serial No. 91,625. (No model.)

Claim.—1. A last-making machine, having, in combination, a last-support, two arms arranged at an angle to each other to form a V-shaped block from the last and a saw arranged at an angle to one of said arms and extending outside of each angle to cooperate with said arms to separate the last part from the free part of the last, said last-support and arms being relatively movable to bring the last and arms into engagement, and the plane in which said arms are located being parallel to the line of each movement, substantially as described.

2. A last-making machine, having, in combination, a last-support, two arms arranged at an angle to each other to form a V-shaped block from a last, and a saw located at the rear of said arms arranged at an angle to one of said arms and extending outside of each angle to cooperate with said arms to separate the last part from the free part of the last, said last-support and arms being relatively movable to bring the last and arms into engagement and the plane in which said arms are located being parallel to the line of each movement, substantially as described.

3. A last-making machine, having, in combination, two arms arranged at an angle to each other to form a V-shaped block from a last, a saw arranged at an angle to one of said arms and extending outside of each angle to cooperate with said arms to separate the last part from the free part of the last and a last-support provided with grooves to receive the arms, said arms and saw and last-support being relatively movable to bring the last and arms into engagement, and the plane in which said arms are located being parallel to the line of each movement, substantially as described.

4. A last-making machine, having, in combination, two arms arranged at an angle to each other to form a V-shaped block from a last, a saw arranged at an angle to one of said arms and extending outside of each angle to cooperate with said arms to separate the last part from the free part of the last, a last-supporting member provided with grooves to receive the arms, said arms and saw and last-support being relatively movable to bring the last

and move into engagement, and the means in which said move are located being parallel in the line of such movement, and adjusting means for bringing the move and standard into proper relative position, substantially as described.

3. A last-curing machine, having, in combination, two move arranged at an angle to each other to saw a V-shaped block from a last, means for adjusting said move longitudinally of their axis, a saw arranged at an angle to one of said move and extending outside of such angle to cooperate with said move to separate the heel part from the fore part of the last, means for adjusting said saw transversely to its axis, a last-supporting standard provided with grooves to receive the move, said move and standard being relatively movable to bring the last and move into engagement, and the means in which said move are located being parallel to the line of such movement, and means for adjusting said standard transversely to its axis, substantially as described.

4. A last-curing machine, having, in combination, a last-support, two move arranged at an angle to each other and a saw arranged outside and in a plane intersecting such angle, said support and move being relatively movable past each other and the means of the latter intersecting in the line of such movement, substantially as described.

698,007. PLUG FOR WATER AND STEAM COCK. IRVING H. GARDNER, Cleveland, Ohio. Filed July 21, 1901. Serial No. 70,204. (No model.)

Claim.—1. A plug for steam and water cocks having a cap seat about the top portion thereof and a removable stop within said cap, in combination with a coupling having a seat for said plug and a projection on said coupling in position to be engaged by said stop, substantially as described.

2. In water and steam cocks, a coupling having a seat with a circular upper portion projecting above the body of the coupling and lugs on the top thereof, in combination with a plug having an integral cap about its top controlling the said upper portion of the seat, and a removable stop in said cap to engage said lugs, substantially as described.

3. The coupling having a seat for a plug provided with a circular extension about its top and lugs on the top of said extension, in combination with a plug having a cap integral with its upper portion and including said lugs and circular extension from above, and a removable stop in the cap arranged to engage against said lugs when the plug is rotated, substantially as described.

4. As a new article of manufacture, a plug for water and steam cocks having a tapered barrel and a cap and handle cast integral with its upper portion, said barrel having a fluid-passage through its center and a hole through its cap for the insertion of a stop, substantially as described.

698,008. CHANGE-GEARING. GEORGE W. GRAVER, Hartford, Conn., assignor to Pratt & Whitney Company, Hartford, Conn. Filed Jan. 11, 1902. Serial No. 69,377. (No model.)

Claim.—In change-gearing, the combination, substantially as set forth, of two change-gears of a train, means for varying the gap between said two gears, an arm mounted for angular adjustment on an axis parallel with the axis of the change-gears, an arm mounted on the first-mentioned arm and angularly adjustable thereon on an axis parallel with the axis of the change-gears, and intermeshing gears carried by said second arm and adapted to engage the change-gears and fill the variety of gaps therebetween.

698,009. GAS STOVE OR RANGE. GEORGE W. GRAVER, Rochester, N. Y., assignor to John F. Miller, Jr., Port Chester, N. Y. Filed Aug. 1, 1901. Serial No. 70,691. (No model.)

Claim.—1. The combination with a gas-stove having an oven or chamber, and a burner arranged outside of the chamber and having orifices, of a tubular flame-conductor having its open inner end extending one or more of said orifices in the burner and its outer end opening into the oven.

2. The combination with a gas-stove having an oven or chamber, a door therefor, and a burner arranged outside of said chamber and having orifices, of a flame-conductor having its inner end extending in proximity to the burner-orifices and its outer end opening into the oven.

3. In a gas-stove the combination with an oven or chamber open at one side and having a door, and a burner arranged beneath the oven, of a conductor having its inner end extending over a portion of the burner and having its outer end opening into the bottom of the oven within the door-line.

4. In a gas-stove the combination with an oven or chamber, a burner extending beneath the oven, and a conductor having its inner end open and extending over the burner and forming a hood and having its outer end opening into the oven-chamber, of a second burner located in the rear of the first having an extension provided with perforations and opening beneath the hood on the conductor.

5. In a gas-stove the combination with an oven having a bottom provided with apertures, of forward and rear burners arranged beneath the bottom, doors normally closing the apertures, and connections between the doors whereby they may be operated simultaneously.

6. In a gas-stove the combination with an oven or chamber, and a conductor leading therefrom having its outer end opening into the oven and its lower end open and extending beneath the latter, of a burner having orifices, a tube extending from said burner having a series of orifices in its lower side and provided with an aperture in its upper side opening beneath the conductor and extending around the tube whereby the flame from said aperture may be communicated to the gas emitted from the series of apertures in its lower side.

7. In a gas-stove the combination with an oven or chamber, and a conductor leading therefrom having its outer end opening into the oven and its lower end open and extending beneath the oven-bottom, of a burner having orifices arranged in its lower side and opening into the oven, a second burner arranged in rear of the first, having gas-jet orifices, an extension on said burner having perforations in its lower side arranged in proximity and leading into juxtaposition with the gas-jet orifices and provided with the apertures opening beneath the inner end of the conductor.

8. In a gas-stove the combination with a body having a heating-chamber, and an oven or chamber located above the latter provided with an apertured bottom, and means for closing said aperture, of a burner located beneath the oven-bottom, and a removable heat-reflecting plate arranged in the heating-chamber below the burner.

698,010. BURNER FOR BAKING-OVEN. GEORGE W. GRAVER, Rochester, N. Y., assignor to John F. Miller, Jr., Port Chester, N. Y. Filed Oct. 2, 1901. Serial No. 71,361. (No model.)

Claim.—1. The combination with an oven-chamber open at one side, and a door normally closing said opening, of a gas-burner arranged

exteriorly of the chamber, and an extension of said burner leading into the oven and accessible when the oven-door is opened.

2. The combination with an oven-chamber having a door at one side thereof, of a burner located at one side of the oven, and having an extension thereof leading into the oven.

3. The combination with an oven-chamber having a bottom provided with an aperture, of a burner arranged beneath the oven, and a perforated tubular extension of said burner accessible through the aperture in the oven-bottom.

4. The combination with an oven-chamber having a bottom provided with an aperture, and a closure for said aperture, of a burner arranged beneath the oven, and a perforated tubular extension leading from the burner and having its outer end extending upwardly in proximity to the aperture in the oven-bottom and provided with a series of gas-jet orifices.

5. The combination with an oven-chamber having a bottom provided with an aperture, and a closure therefor, of separate gas-burners arranged beneath the oven, separate supplemental burners attached to each burner having their outer ends arranged in proximity beneath the aperture in the oven-bottom.

698,011. TUCK-CREASER FOR SEWING-MACHINES. JOHN H. GARDNER, New Haven, Conn. Filed June 1, 1901. Serial No. 69,794. (No model.)

Claim.—1. In a sewing-machine tuck-creaser, the combination with means for attaching the tuck-creaser to a sewing-machine, of creasing device comprising a vibrating creasing arm or lever, an operating-lever, a transmitting-lever consisting of a rod or wire arranged to be engaged by said operating-lever and having right-angular bends at its opposite ends one of which serves to pivot said lever and the other of which engages the said creasing arm or lever, and a spring, independent of said transmitting-lever, for lifting the latter after it has been depressed, said transmitting-lever being engaged between its ends by the said operating-lever.

2. In a sewing-machine tuck-creaser, the combination with the frame thereof comprising the pressure-foot a having a laterally-extending arm or plate b provided at its end with an ear c, of an operating-lever d pivoted to a part of the shaft of said pressure-foot, creasing device comprising a creasing arm or lever e, extending lengthwise the attachment, and a co-operating lip or part, a transmitting-lever f actuated by said lever c and having at its rear end a right-angular bend or arm g pivotally mounted in the said ear c and having at its forward end a right-angular bend or arm h overlying the said creasing arm or lever e, and a spring i for lifting the transmitting-lever after it has been depressed.

698,012. AIR-ESCAPE VALVE. AUGUST GRAVER, Cologne, Germany. Filed Sept. 12, 1901. Serial No. 73,942. (No model.)

Claim.—An air-escape valve for operating the air-brakes of a car or train from the rear-end, the distinguishing feature of which is that the valve-cap or cylinder-head A is fastened to a lever d by means of a threaded spindle f and through which the cap or cylinder-head A is held in place at the end of the cylinder c so that the main lever p through its roller e bears upon the way n.

698,013. COOLING-TOWER. WILLIAM H. A. HARRIS and RALPH L. LAPHAM, Charleston, S. C. Filed Oct. 15, 1901. Serial No. 72,722. (No model.)

Claim.—1. A cooling-tower having cooling-coils in the base thereof, means to evaporate water in the upper portion of the tower, and to discharge cooled water onto said coils, and a deflector above the latter, to prevent air heated by said coils from passing into the upper, evaporating portion of said tower, substantially as described.

2. A cooling-tower having means to evaporate water in the upper portion thereof, cooling-coils in the base thereof, means to apply the water cooled in the evaporating-portion of the tower to the coils and a deflector above the said coils to prevent heated air from passing into the upper, evaporating portion of the tower, substantially as described.

3. A cooling-tower to which air is admitted, having means to shower water downwardly in the upper portion thereof, a series of descending steps to retard the descent of the water and promote the evaporation thereof, means to collect the cooled water discharged from the steps, cooling-coils in the base of the tower, means to discharge the cooled water onto the coils, and a deflector above the coils to prevent heated air from passing into the upper, evaporating portion of the tower, substantially as described.

4. A cooling-tower to which air is admitted, having means to shower water downwardly in the upper portion thereof, a series of descending steps to retard the descent of the water and promote the evaporation thereof, cooling-coils in the base of the tower, a deflector above the coils to prevent heated air from passing into the upper evaporating portion of the tower, and means to discharge the cooled water from the steps onto the coils, substantially as described.

698,014. LOCKED BOOK-HOLDER AND ARM-REST. WILLIAM F. HARRIS, New Haven, Conn. Filed May 1, 1901. Serial No. 69,222. (No model.)

Claim.—1. An improved book-holder comprising in combination a frame, a flat strip 24 rotatably mounted in the frame, spring-plates 27 adjustably secured to the under surface of the strip 24 and capable of engaging and yieldingly supporting the back of the book between them, for the purpose stated.

2. An improved book-holder, comprising in combination a frame, a strip rockingly mounted in the frame, means for detachably securing the back of the book to said strip, and rollers mounted in said frame on opposite sides of the strip to engage and support the sides of the book, for the purpose stated.

3. An improved book-holder, comprising in combination a frame, a flat strip rockingly mounted in said frame, means for applying friction to the said strip so that its rocking movement is resisted, clamping devices fixed to the said strip to engage the back of a book and firmly hold it in position adjacent to the strip, and means for supporting the sides of the book having its back resting on said strip for the purpose stated.

4. An improved book-holder comprising a frame having two vertical, parallel end pieces, means for adjusting these end pieces to and from each other, a flat strip rockingly mounted between said end pieces, clamps on said strip to engage and support the back of a book between them, and means for supporting the sides of a book having its back resting between said clamps for the purpose stated.

698,015. PHOTOGRAPH-PRINTING FRAME. FRIEDRICH EISEN, Berlin, Germany. Filed Dec. 4, 1901. Serial No. 84,948. (No model.)

Claim.—In a photograph-printing frame, the combination with the frame *a*, of a two-part back *b* and *c*, a hinge *e* connecting the two parts of the back, a hinge *f* connecting the back with the frame, a spring *h* adapted to press the back against the frame, and a spring *g* adapted to press the hinged part of the back separately against the frame, for the purpose as described.

698,016. CYAND-TANK. JAMES J. HERVEY, Randolph, Cal. Filed Nov. 28, 1901. Serial No. 85,495. (No model.)

Claim.—1. A tank having an annular lining open at the bottom, said lining having air and water pipes leading thereto, substantially as described.

2. A cyand-tank having an annular lining open at the bottom said lining being divided into a series of compartments, each compartment having an air and a water tank communicating therewith, substantially as described.

3. A cyand-tank having a tapering bottom and the central cone arranged in connection with the said tapering bottom, the annular lining arranged upon the interior of the tank and having air and water pipes connected thereto, and the charging and discharging pipes leading to and from the bottom of the tank, substantially as described.

4. Cyand-tank having a tapering bottom and a central cone arranged in connection with the bottom, an annular lining arranged in the tank and open at its lower end, a filtering-cone connecting the lower end of the lining and the central cone, the air and water pipes, the charging and discharging pipes, and the filtering means connected with said pipes, substantially as set forth.

698,016.

698,017. GAS-HEATER. FRANK C. HODGKINS, Brooklyn, N. Y. Filed Aug. 16, 1901. Serial No. 71,602. (No model.)

Claim.—A gas-heater, consisting of a cylindrical casing provided with air-inlet openings, a rim secured to the lower edge of said casing and provided with an inwardly-projecting flange, transverse bracing attached to said flange, a burner supported on said bracing, means for supplying gas to said burner, and a top ring attached to the upper part of the casing and provided with radial outlet-grooves and raised ribs between said grooves, substantially as set forth.

698,018. ANSWER-REPLY. GUYMON E. HODGKINS and GUYMON E. HODGKINS, Chicago, Ill., assignors to the Stromberg-Carlson Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Nov. 27, 1901. Serial No. 77,595. (No model.)

Claim.—1. In an answerer, the combination with the operating-magnet thereof, of a shutter, means controlled by the magnet for releasing the shutter, means including the shutter for coupling said electromagnet, and means operated by the electromagnet for returning the shutter, substantially as described.

2. In an answerer, the combination with the shutter thereof, of means for releasing the same, an electromagnet having its armature adapted to attract the shutter, and means including the shutter for coupling

the electromagnet to effect an attraction of the armature and thereby the restoration of the shutter, substantially as described.

3. In an answerer, the combination with the shutter thereof, of means for releasing the same, an electromagnet having its armature adapted to attract the shutter, and means for coupling the electromagnet to effect an attraction of the armature, and thereby the restoration of the shutter, the said releasing means being also operated by the said electromagnet, substantially as described.

4. In an answerer, the combination with the shutter thereof, of a retaining-lever for holding the shutter in its normal idle position, an electromagnet having its armature adapted to attract the shutter, and means for coupling the electromagnet to effect an attraction of the armature and thereby the restoration of the shutter, the retaining-lever being articulated to the armature and having a limited lost motion with respect to the armature, substantially as described.

5. In an answerer, the combination with the shutter thereof, provided with an extension *a*, of a retaining-lever for holding the shutter in its normal idle position, an electromagnet, a push-rod intervening between the armature of the electromagnet and the said extension *a*, and means for coupling the electromagnet to effect the attraction of the push-rod and the restoration of the answerer-shutter through the engagement of the push-rod with the extension, the retaining-lever being articulated to the armature and having a limited lost motion with respect to the armature, substantially as described.

6. The combination with an electromagnet provided with a shutter and means for returning the shutter in a normal position, the armature of the electromagnet serving to effect the operation of the said means, a circuit for coupling the said electromagnet to effect the operation of the said shutter-releasing means and thereby the release of the shutter, the said armature being adapted to attract the shutter upon the release of the latter, a second circuit normally provided with two openings also for coupling said electromagnet, means whereby the shutter in falling may close one of the said openings, and means whereby the second opening of the returning-circuit may be closed to thereby effect the operation of the armature and the restoration of the shutter, substantially as described.

7. The combination with the shutter of an answerer, of means for effecting the release of the shutter, an electromagnet whose armature is adapted to attract the shutter when the latter is released, a returning-circuit adapted to include the said electromagnet and provided with two openings, means whereby the shutter in being released may close one of the said openings, and means for closing the remaining opening, whereby the said armature may be attracted to effect the restoration of the shutter, substantially as described.

8. The combination with the shutter of an answerer, of means for effecting the release of the shutter, an electromagnet whose armature is adapted to attract the shutter when the latter is released, a returning-circuit adapted to include the said electromagnet and provided with two openings, means whereby the shutter in being released may close one of the said openings, and means for closing the remaining opening, whereby the said armature may be attracted to effect the restoration of the shutter, the same armature also having operative connection with the shutter-releasing means, whereby it may act in the double capacity of effecting the release of the shutter, and its restoration, substantially as described.

9. The combination with a signal-revealing means, of means for actuating the signal-revealing means, an electromagnet for effecting the restoration of the signal-revealing means, a returning-circuit including the electromagnet and provided with two openings, means whereby the signal-revealing means may close one of the said openings when the signal-revealing means is operated to reveal the signal, and means for closing the second opening of the said circuit, substantially as described.

10. The combination with a signal-revealing means, of means for actuating the same to effect a signal, means for returning the signal-revealing means, manually-operated means for controlling the operation of the returning means in part, and means controlled by the signal-revealing means serving in conjunction with the manually-operated means to jointly govern the returning means, substantially as described.

11. The combination with signal-revealing means, of means for actuating the same to effect a signal, means for returning the signal-revealing means, controllable means for controlling the operation of the returning means in part, and means controlled by the signal-revealing means serving in conjunction with the controllable means to jointly govern the returning means, substantially as described.

12. The combination with an electromagnet provided with a shutter and means for returning the shutter in a normal position, the armature of the electromagnet serving to effect the operation of the said means, a circuit for coupling the said electromagnet to effect the operation of the said shutter-releasing means and thereby the release of the shutter, the said armature being adapted to attract the shutter upon the release of the latter, a second circuit having two openings also for coupling the said electromagnet, whereby the said armature may again

be attracted to effect the restoration of the shutter, means whereby the shutter when falling may close one of the said openings, and means for closing the remaining opening to close the second circuit, substantially as described.

13. A signal provided with a single coupling-coil adapted to effect the presentation thereof, signal-revealing means, and means whereby the said coil may be operated to effect the operation of the signal-revealing means, substantially as described.

698,019. DIE FOR DIE-MACHINING. CLAUDE HOLLEY, Albany, N. Y., assignor to Chambers Brothers Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Nov. 12, 1901. Serial No. 84,948. (No model.)

Claim.—1. In a roller-die for brick-machining, the combination of two rollers having the beveled flanges at alternate ends only, and the correspondingly-beveled and portions opposed to said flanges respectively, the inner sides of said flanges flaring with the body of the rollers, the die-opening, substantially as set forth.

2. In a roller-die for brick-machining, the combination of the two independently-rotatable rollers having the beveled flanges at alternate ends only, and the correspondingly-beveled and portions opposed to said flanges respectively, said rollers being adapted to be rotated by the bar of clay in passing between them, and the inner sides of said flanges flaring with the body of the rollers the die-opening, substantially as set forth for the purpose set forth.

698,020. METHOD OF MAKING WELLS. JAMES C. BOWMAN, Penn. Pa. Filed Sept. 2, 1901. Serial No. 74,948. (No model.)

Claim.—1. The method of making wells which consists in cementing the well, forming a tubular impervious casing for the well as the cementing progresses, opening up holes in that part of the casing that passes through water-bearing strata, preventing seepage through the holes in the casing and causing the strata to be sealed.

2. The method of making wells which consists in cementing the well, forming a tubular impervious casing for the well as the cementing

progress, opening up holes in that part of the casing that passes through water-bearing strata, stirring the strata adjacent to the holes, protruding strainers through the holes in the casing and covering the strainers to the casing.

698,021. NORMS-DETACHER. FRANK H. EMM, Resend, Ga. Filed July 26, 1901. Serial No. 69,731. (No model.)

Claim.—In combination, a singletree having a truss-rod at each end, truss-pins for holding the trusses on the respective truss-locks, a throw-off lever pivoted at each end of the singletree, the forward end of each lever being bifurcated and having its two arms embrace the singletree proper, one arm above and the other beneath the singletree, both arms lying just inside of the shoulder at the end of the singletree, both said arms being curved forward and inward from a point opposite the truss-locks, and means for withdrawing the truss-pins and operating the throw-off levers, for the purpose set forth.

698,022. ELECTRIC MARRIAGE-MACHINE. EDWARD J. JACOBSON, Boston, Mass., assignor, by mesne assignments, to Thor H. Hoffman, Boston, Mass. Filed Sept. 12, 1900. Serial No. 730,314. (No model.)

Claim.—1. A massage instrument comprising an intermittently-acting percussive impact member, and a guard for limiting the approach of said instrument to the body under treatment.

2. A massage instrument comprising a vibrating percussive implement, and a guard for limiting the impact of the same on the subject under treatment.

3. A massage instrument comprising an electrically-actuated impact-vibrator, and mechanical means continuously under the control of the operator for governing the vibration thereof.

4. A massage implement comprising an electrically-actuated impact-vibrator connected with an electric circuit, and an electrically-actuated member in proximity to the vibrator.

5. A massage mechanism comprising a casing adapted for conventional handling, an electromagnetically-actuated vibrator contained within the casing and having a percussive portion extending outside the casing, and a mechanical controller for said vibrator working through an opening in the casing.

6. A massage mechanism comprising an electromagnetically-actuated guard-frame, and a percussive implement working in said frame.

7. A massage mechanism comprising an electromagnetically-actuated vibrator and a pair of electromagnets the cores of which are extended to form a frame for the vibrator.

8. A massage implement comprising tubular electromagnets with cores respectively mounted therein, means for adjusting the cores longitudinally, and a frame connected with said cores.

9. A massage mechanism comprising a casing, an electromagnetically-actuated vibrator contained therein and having a percussive arm extending therefrom, an electromagnet mounted on the casing, and a frame, adjustable with relation to the percussive arm electrically connected with said magnet.

10. A massage mechanism comprising a casing, an electromagnetically-actuated percussive implement mounted therein and having a portion extending therefrom, arms mounted for longitudinal adjustment on the casing and carrying a frame which partially embraces the outer portion of the percussive implement, and means for adjusting the arms.

11. The combination with the casing 6 having the handle 5 and the open end, of the plate 7 for closing the end and having the ears 8 and the stud 9, the screw 10 secured in the stud 9 and insulated therefrom, the post 12 on said screw, the block 15 pivotally supported in the ears 8 and having the armature 16 furnished with the springs 17 and 18 and the arm 19, the magnet-frame comprising the plate 21 and arms 20 20, the magnets secured to said plate, and the controller-rod 24 reciprocal in a bearing in the plate 21, bearing on the spring 18 and having the button 25 working in an opening in the casing.

12. The combination with the casing 6, the frame 26 mounted thereon and provided with the screw-threaded sleeve 28, and the magnets 27 27 in said frame, of the screw 29 29 reciprocal in said magnets and having the bent-up arm 31 31 connected by the strip 32, the cross-plate 33 secured to the rear ends of the screw 29 29, and the adjusting-screws 34 rotatable in said cross-plate and engaging the screw-threaded sleeve 28, as and for the purpose described.

698,023. FLOW. ALAN KAP, High Road, Niam. Filed Oct. 20, 1901. Serial No. 69,898. (No model.)

Claim.—1. In a plow, the combination of wheels, an axle, a frame carried by the axle, one of the wheels mounted within the frame, a frame mounted upon both sides of the wheel within the frame, a gang-coupling located in rear of the axle connecting the plow-gangs to permit independent vertical movement thereof, and a lock-lever for diverting the plows.

2. In a plow, the combination of plow-beams, a frame, an axle and wheels mounted in the frame, whereby the lower wheel runs between the plow-beams, and a gang-coupling for the plow-beams located in rear of the axle permitting independent vertical movement of each of the plows.

3. In a wheel-plow, the combination of two plows, a coupling directly connecting the two beams of the plow-gangs, said coupling comprising vertical bearings which permit the independent rise and fall of each plow-beam.

4. A gang-plow coupling comprising two members, each provided with clips for securing the plow-beam thereto and each provided with lower projecting members having vertical sliding bearings, whereby one member of the coupling may have a vertical movement with respect to the other.

698,024. GOLF-BALL. RICHARD KIRCHMANN, Boston, Mass., assignor to The Kongsbak Manufacturing Company, a Corporation of New Jersey. Filed Mar. 24, 1902. Serial No. 98,619. (No model.)

Claim.—1. A playing-ball comprising a spherical body consisting of rubber threads under tension, a fabric covering upon said body, and a gutta-percha shell upon said fabric covering.

2. A playing-ball comprising a sphere which consists of tensioned soft rubber, a shell consisting entirely of gutta-percha lined with fabric and including said sphere.

3. A playing-ball comprising a sphere which consists of tensioned soft rubber, and a shell consisting entirely of gutta-percha lined with fabric and including said sphere and holding said sphere under compression.

4. A playing-ball comprising a spherical body consisting of tensioned rubber threads, and a fabric-lined shell of gutta-percha compressed upon said spherical body.

5. A playing-ball comprising a spherical body consisting of tensioned rubber threads and a fabric-lined shell of gutta-percha compressed upon said spherical body, said shell consisting of segments of gutta-percha and fabric which are united at their edges.

6. A playing-ball consisting of a spherical body of soft rubber under tension, a fabric covering thereon, and segments of gutta-percha welded at their edges and compressed upon said spherical body.

7. A playing-ball comprising a soft-rubber spherical core enclosed in an envelope of fabric, and an outer including covering of gutta-percha compressed upon the ball.

698,025. TELEPHONE-BOOTH. CHARLES L. KIRK, Indianapolis, Ind. Filed Jan. 26, 1901. Serial No. 65,109. (No model.)

Claim.—1. A telephone-booth the walls of which are formed of a series of casings spaced from each other and having a continuous unbroken air-space between the casings, and distance-bars arranged between the casings at each side of said air-space, whereby the spaces at each side of the air-space are divided into a series of independent air-cells.

2. A telephone-booth the walls of which are formed of a series of casings spaced from each other and having a continuous unbroken air-space between the casings, the space formed by the casings at each side of said air-space being divided into a series of air-cells, a pair of inner doors arranged at one side of the booth, a pair of outer doors spaced from said inner doors, and connections between the inner and outer doors for simultaneously moving the doors in opposite directions.

3. In a telephone-booth, the combination with the doorway thereof, of the inner and outer doors arranged in pairs, and means for connecting said doors, whereby one of the pairs is adapted to simultaneously swing in opposite directions to the opening pair.

4. In a telephone-booth, the combination with the doorway thereof, of inner and outer doors arranged in pairs and each comprising inner and outer casings formed of sound-deadening material, and means for connecting said doors, whereby one of the pairs is adapted to simultaneously swing in opposite directions to the opening pair.

5. In a telephone-booth, the combination with a series of casings spaced from each other in form the walls of the booth and having a continuous unbroken air-space between the casings, of a window-cash arranged in the inner casings and provided with a light, and a window-cash arranged in the outer casings and also provided with a light, said outer cash extending over the centrally-arranged air-space and being provided with a series of vent-openings for connecting the air-space intermediate the window-cashes with the centrally-arranged air-space.

698,026. PROCESS OF KNEEDING. WILLIAM KRAMER, Berlin, Germany, assignor to The Firm of J. & H. Kramers, Berlin, Germany. Filed Apr. 2, 1907. Serial No. 98,621. (No specimen.)

Claim.—1. The method herein described of kneading cotton fiber which consists in loosely supporting the fibers and imparting each a swift rotary movement thereto during the process of kneading and washing as will prevent the longitudinal shrinkage of the material while causing the kneading liquid to pass through the fiber from the interior thereof in one direction, and subsequently washing the fiber during rotation.

2. The method herein described of kneading cotton fiber, which consists in loosely supporting the fibers to be treated, imparting a swift rotary movement to the fibers that will overcome the tendency to shrink while forcing the kneading liquid in one direction through the supported fibers during each rotary movement, and subsequently forcing the washing liquid through the fibers in the same direction during each rotary movement.

3. The within-described improvement in kneading cotton which consists in subjecting the material to the action of centrifugal power of each degree that it will overcome the centrifugal carry of the liquid employed, substantially as set forth.

698,027. POLARIZED MAGNET. BROWN & KRAFT, Syracuse, N. Y. Filed May 26, 1901. Serial No. 68,312. (No model.)

Claim.—1. A polarized magnetic device comprising a magnet having its two ends branched or forked each into a pair of magnetic poles of the same polarity but each of said poles being of opposite polarity, all four poles so formed lying in the same plane and each of said poles forming, or marking, opposite sides of a rectangular therein; a second magnet having two poles of opposite polarity, each of which is located at or near one extremity thereof and between a positive and a negative pole of those of said first magnet forming said rectangles; an axle passing through the geometrical center of said rectangles and perpendicular to the plane thereof upon which said axle one of said magnets is pivotally mounted; and means to control the magnetic condition of one of said magnets.

2. A polarized magnetic device comprising a magnet having its two ends branched or forked each into a pair of magnetic poles of the same polarity but each of said poles being of opposite polarity, all four poles so formed lying in the same plane and each of said poles forming, or marking, opposite sides of a quadrilateral figure therein; a second magnet having two poles of opposite polarity each of which is located at or near one extremity thereof and between a positive and a negative pole of those of said first magnet forming said quadrilateral figure; an axle passing through the center of gravity of said quadrilateral figure and perpendicular to the plane thereof; and means to control the magnetic condition of one of said magnets.

similar to the plane thereof upon which one of said magnets is pivotally mounted; and means to control the magnetic induction of one of said magnets.

2. A polarized magnetic device comprising an electromagnet having its two ends branched or forked each into a pair of magnetic poles of the same polarity but each of said pairs being of opposite polarity, all four poles so formed lying in the same plane and each of said pairs forming or marking opposite sides of a rectangular figure therein; a permanent magnet having two poles of opposite polarity each of which is located at or near one extremity and between a positive and a negative pole of these of said electromagnet forming said rectangle; an axis passing through the geometrical center of said rectangle and perpendicular to the plane thereof upon which said permanent magnet is pivotally mounted; and means to control the magnetic induction of said electromagnet.

3. A polarized magnetic device comprising an electromagnet having its two ends branched or forked each into a pair of magnetic poles of the same polarity but each of said pairs being of opposite polarity, all four poles so formed lying in the same plane and each of said pairs forming or marking opposite sides of a quadrilateral figure therein; a permanent magnet having two poles of opposite polarity each of which is located at or near one extremity and between a positive and a negative pole of these of said electromagnet forming said quadrilateral figure; an axis passing through the center of gravity of said quadrilateral figure and perpendicular to the plane thereof upon which said permanent magnet is pivotally mounted; and means to control the magnetic induction of said electromagnet.

4. A polarized magnetic device comprising two magnets, one at least of which is subject to the direct influence of a magnetizing-cell adapted to reverse its polarity, the first of said magnets having its extremities branched or forked each into two magnetic poles all lying in the same plane and marking the corners of a rectangle therein, the second magnet having two poles of opposite polarity located each at or near an extremity thereof, and between a positive and a negative pole of these of said first magnet outlining said rectangle; an axis passing through the geometrical center of said rectangle and perpendicular to the plane thereof upon which one of said magnets is pivotally mounted and adapted to swing in such a manner as to place its magnetic lines in continuation with those of the other magnet thus forming through both magnets from end to end a single continuous magnetic circuit whose direction in either magnet is unchanged by a reversal in the other.

5. A polarized magnetic device comprising an electromagnet having its two ends forked each into two branches of equal magnetic resistance, terminating in a pair of magnetic poles of the same polarity, but each of said pairs being of opposite polarity, all four poles so formed lying in the same plane and each of said pairs forming or marking opposite sides of a quadrilateral figure therein; a permanent magnet having two poles of opposite polarity each of which is located at or near one extremity and between a positive and a negative pole of these of said electromagnet forming said quadrilateral figure; an axis passing through the center of gravity of said quadrilateral figure and perpendicular to the plane thereof upon which one of said magnets is pivotally mounted; and means to control the magnetic induction of said electromagnet.

6. A polarized magnetic device comprising two magnets, one at least of which is subject to the direct influence of a magnetizing-cell adapted to reverse its polarity, the first of said magnets having its extremities divided each into two branches of equal magnetic resistance, each branch terminating in a magnetic pole and all poles so formed lying in the same plane and marking the corners of a rectangle therein, the second magnet having two poles of opposite polarity located each at or near an extremity thereof and between a positive and a negative pole of these of said first magnet outlining said rectangle; an axis passing through the geometrical center of said rectangle and perpendicular to the plane thereof upon which one of said magnets is pivotally mounted and adapted to swing in such a manner as to place its magnetic lines in continuation with those of the other magnet thus forming through both magnets from end to end a single continuous magnetic circuit whose direction in either magnet is unchanged by a reversal in the other.

698,098. TWIN RAY-PULP PULP SEPARATING. ROBERT KRAFFT, Karlsruhe, Germany. Filed May 6, 1904. Serial No. 69,394. (No apparatus.)

Claim.—As a new article of manufacture, a machine consisting of an inner and outer layer and an intermediate layer of pulp composed of a mixture of finely-ground turf, glycerine, starch, paper-pulp and a small percentage of an antiseptic, such as carbolic acid, substantially as described.

698,099. LIFE-GUARD FOR FIRE-ENGINE. HARRY KIMMER and EDWARD J. HOFFMAN, Minneapolis, Minn.; said Kimmer assignor to said Hoffman. Filed Aug. 1, 1905. Serial No. 79,479. (No model.)

Claim.—1. A life-guard for use comprising a pivoted lever having a thumb or finger piece and a line-guide, through the latter of which the line is passed, substantially as described.

2. A life-guard for use, comprising a lever pivoted at its intermediate portion to a suitable support and provided at one end with a thumb-piece and at its other end with a guide-loop, through which loop the line is passed, substantially as described.

3. A life-guard for use, comprising a lever pivoted at its intermediate portion and provided at one end with a thumb-piece and at its other end with an adjustable guide-loop through which the loop-line is passed, substantially as described.

4. A life-guard for use, comprising the lever pivoted to a suitable support at *f* and provided at one end with a thumb-piece *a'* and at its other end with the guide-loop *b*, having the stem *b'* adjustably secured to the body of said lever *a* by one or more screws *c*, substantially as described.

698,080. WINDOW-WASHING APPARATUS. EDWARD C. LAYTON, Duluth, Minn., assignor, by direct and remote assignments, to Layton's Safety Window Cleaner Company, Minneapolis, Minn., a Corporation. Filed July 17, 1906. Serial No. 59,948. (No model.)

Claim.—1. In a window-washer, the combination of a horizontal tube adapted to be rigidly secured between the sides of the window-frame, of a carriage mounted to slide on said tube, a block pivoted to said carriage, a horizontal tube or bar mounted in said pivoted block, a vertical standard carried by the horizontal tube or bar, and washing device carried by the vertical standard, substantially as described.

2. In a window-washer, the combination of a vertically-arranged hollow standard, a pulley mounted at the upper end thereof, a block slidably secured on the outside of the standard and carrying a window brush or cleaner which always remains outside of the standard, an elastic cord loosely secured at or near the lower end of the standard and extending upwardly therefrom along said standard and passed over the pulley and secured to the under side of the block for automatically raising said block and the brush or cleaner carried thereby each time they are drawn downwardly by the operator, and an indicator cord secured to the under side of the block and extending to a suitable point within easy reach of the operator for drawing the block downward on the standard, substantially as described.

698,081. THE. EDWARD J. LAYTON, Duluth, Minn., assignor to Layton's Safety Window Cleaner Company, a Corporation of New York. Filed Nov. 25, 1904. Serial No. 61,625. (No model.)

Claim.—1. An open-center tile having a concave under surface.
2. An open-center tile provided with a corrugated periphery.

3. A tile cut away centrally to form an opening of varying diameter and having a concave under surface.

4. A tile cut away centrally to form a through-opening and provided with a corrugated periphery, the under surface of said tile being concave.

698,082. FEEDING AND CONVEYING MACHINE. THOMAS LEAH, Cleveland, Ohio. Filed Jan. 27, 1908. Serial No. 61,647. (No model.)

Claim.—1. In a feeding and conveying machine, a reversible device, a traveling adjustable conveyor supported and carried by the device, a receiving-hopper mounted on the frame of the device, and an adjustable telescopic spout attached to the end of the conveyor-belt, and means for opening the same, in combination, substantially as and for the purpose set forth.

2. In a feeding and conveying machine, a reversible device, a traveling adjustable conveyor supported and carried by the device, a receiving-hopper mounted on the frame of the device, in combination with and supported on a vessel having fluid compartments, a tunnel in the bottom of said compartments, a hinged coupling-conveyor in said tunnel, down to the sides of the compartments for delivering their contents into said tunnel, and a vertical inclined conveyor connected with said tunnel, and a discharging spout on the top of said vertical conveyor for transferring material into the receiving-hopper on the device, substantially as described.

698,083. STEAM-POWER WELL-DRILLING MACHINE. GEORGE B. LECHE, Elm, Ohio. Filed June 17, 1906. Serial No. 79,866. (No model.)

Claim.—1. In a well-drilling machine, the combination with a supporting-frame including longitudinal ribs, and a derrick-mast, of inclined beams mounted with their forward ends at the base of the mast and having their rear ends raised above the ribs, a drive-shaft mounted upon the frame at the foot of the mast and carrying a drive-pulley and a drill-rotating crank, a sand-drum mounted between the drive-shaft and the foot of the mast, with its axis in a plane below the axis of the drive-shaft, said sand-drum being adapted for movement into and out of operative relation to the drive-shaft to receive motion therefrom, a bull-wheel mounted upon the ribs in the rear of the drive-shaft and adapted for bodily movement into and out of operative relation thereto, whereby the drive-shaft will have the functions of operating the adjacent sand-drum and bull-wheel, and of operating the drill-rope, the bull-wheel shaft lying below the drive-shaft, and a power-shaft mounted upon the frame in the rear of and below the drive-shaft, and having a belt connecting with the drive-shaft, whereby the drive will be in the direction of the bull-wheel shaft to maintain operable connection therewith.

2. In a well-drilling machine, a frame having a mast, a walking-beam pivotally mounted on the mast and adapted when closed to be turned to a vertical position, a driven shaft having a crank, a connection, including a pinion, to communicate power to said walking-beam from said crank, said pinion being adapted to be attached to and disconnected from the wrist of said crank, a standard on said frame, a spanning pivot supported by said standard and disposed transversely with reference to the frame and at one side thereof, a spreading-lever mounted on said spanning pivot, for lateral movement thereon and having at its lower end a pulley 20, mounted and shiftable laterally on said spanning pivot, with said spreading-lever, the latter having at its outer end a slot 30 adapted for the reception of the wrist of said crank, whereby said spreading-lever may be operated by or unclipped from said crank, and when unclipped therefrom may be free to drop its outer end to the ground, said spreading-lever having a cleave 50 at its outer end, substantially as described.

698,084. MACHINE FOR IMPROVING AND PRINTING. GEORGE B. LECHE, Elm, Ohio. Filed Jan. 10, 1907. Serial No. 61,648. (No model.)

Claim.—1. In an improving and printing machine, the combination with a die, of two rollers, a polishing-rod wound on said rollers and adapted to bear between its ends on said die, means for moving said die in one direction, and means for intermittently moving the polishing-rod and means for automatically rotating one of said rollers to cause the polishing-rod to be wound thereon, substantially as set forth.

2. In a rotary embossing and printing machine, the combination with two cylindrical rotary-carriers, a curved segmental die removably secured

to one of said segmental carriers, and a removable counter-die carried by the other segmental carrier, of an ink-roller, an elastic ink-roller for said die, a polishing-paper means for moving over and in contact with said carrier die, rollers on which said polishing-paper is wound, and means for automatically rotating one of said rollers, substantially as set forth.

3. In an embossing and printing machine, the combination with the embossing and printing die, of a polishing-strip, and vibratory means for drawing a limited and predetermined quantity thereof across the said die, and an automatic take-up for keeping the strip taut.

4. In an embossing-machine, the combination with a die-carrier and a die, of a polishing-strip and means operated automatically by the die-carrier for drawing a limited and predetermined quantity of said polishing-strip across the die.

5. The combination with a reversible die-carrier and a die, of a polishing-paper strip, means for causing said strip to make contact with and move across the die, a gripping device, device intermediate of the die-carrier and gripping device for operating the latter to draw a predetermined amount of polishing-paper across the die, and means for adjusting said intermediate device for regulating the amount of strip to be drawn across the die at each operation of said intermediate device, substantially as set forth.

698,085. ATTACHMENT FOR GRACKER, RESCUE, OR CAKE MACHINES. BAKER, W. HANSEN, Mason, Ga. Filed Dec. 15, 1901. Serial No. 24,009. (No model.)

Claim.—1. An attachment for blanch, cake or cracker machines consisting of a frame having means for applying oil or grease to the face of roller of the machine, and means for subsequently depositing a pulverulent material on the oiled or greased face of the roller.

2. In combination with a compression-roller, of a blanch, cake or cracker machine, of a frame having a chamber which is adapted to receive an absorbent material which is saturated with oil and means for depositing pulverulent material upon the oiled surface of the roller.

3. In a dough-preparing machine, the combination with a roller, means for applying oil to the surface of the roller, means for subsequently

dusting the roller with a pulverulent material which is placed on the dough so that the oil will be apparent, for the purpose set forth.

4. In a dough-preparing machine, the combination with one of the compression-rollers thereof of means for applying an oleaginous substance to the surface of the roll, a vertically-vibrated hopper for applying a pulverulent material thereon upon the oiled surface of the roll, for the purpose set forth.

5. In combination with a compression-roll of a cracker, blanch or cake forming machine, of a frame having a compartment which is open to the roll, a scraper, and a vertically-vibrated hopper, substantially as shown.

6. An attachment for cracker, blanch or cake forming machine, consisting of a frame having a chamber which is open to a compression-roller of the machine, a scraper, a hopper maintained to be susceptible of a vertical movement in the frame, a drive carried by the hopper, camshafts with which the hopper contacts, a rock-shaft having arms which engage the hopper, means for rocking the shaft, and springs to effect a quick return of the hopper, substantially as shown and for the purpose set forth.

698,086. MOTOR-VEHICLE. CHARLES L. MAYNOR, Saratoga Springs, N. Y. Filed May 21, 1901. Serial No. 61,904. (No model.)

Claim.—1. The combination with a motor and its casing, of the motor-shaft, bearings carried by the motor-casing concentric with the shaft, a hanger including spaced arms swingingly mounted upon the bearings, a drive-shaft mounted in the hanger and operatively connected with the motor-shaft, a driving member upon the drive-shaft, and means connected with the hanger for holding the power-shaft in constant speed relation with an axle to be driven.

2. The combination with a motor and its shaft, of a hanger swingingly mounted concentric with the shaft, a drive-shaft mounted in the hanger and having a drive member, a brake-drum connected with the drive member, projections upon the hanger extending beyond the brake drum, and brake mechanism mounted in the projections in operative relation to the drum.

3. The combination with a motor and its shaft, of a hanger mounted concentric with the shaft for swinging movement, a drive-shaft mounted in the hanger and operatively connected with the motor-shaft, a drive-sprocket mounted upon the drive-shaft, clutch mechanism for throwing the sprocket into and out of operative relation to the drive-shaft, a chain engaged with the sprocket, a chain-tightener carried by the hanger in operative relation to the chain, brake mechanism for the sprocket carried by the hanger, and means connected with the hanger for holding the drive-shaft in speed relation to an axle to be driven.

4. The combination with a motor and its shaft, of a hanger comprising spaced vertical arms 6 and 9 each having forwardly and rearwardly extending arms 10 and 11, of a drive-shaft 12 mounted in the hanger and operatively connected to the motor-shaft, a driving-sprocket 20 mounted on the drive-shaft, a clutch-disk 21 loosely mounted on the drive-shaft, a sliding clutch carried by said shaft and adapted to engage with the disk, brake-drum carried by the drive-shaft, hand-brake members 22 and 23 having one end fixedly secured to a portion of the hanger-frame, and adjustable spacing-bars connecting the hanger-frame to the driving-shaft of the vehicle, substantially as specified.

698,087. SUPPORTING MEANS FOR GARMENTS. CHARLES W. HENRY, Chicago, Ill. Filed Oct. 2, 1901. Serial No. 73,897. (No model.)

Claim.—1. A garment-support comprising in combination with the strengthening-web and the inner-lining fabric of a waistband, a relatively thin U-shaped hook, upwardly-extending parallel arms extending above the top of the hook portion and terminating in rearwardly-directed sharp points, said hook and arms being passed upwardly through the lining fabric and between said lining fabric and strengthening-web and having the extremities thereof permanently attached to the strengthening-web at points above the hook.

2. The combination with the waistband of a garment comprising an inner web of canvas and an inner lining of fabric of a relatively thin hook having rounded wearing-surfaces and comprising an arm adapted to be passed through and concealed between the lining fabric and canvas and permanently attached to the canvas web without cutting either fabric and the attachment with the canvas being above the hook.

3. In a pair of trousers, the combination with the waistband comprising a strengthening-web and an inner lining of a relatively thin hook having upwardly-directed thin pointed arms, said arms being passed through the lining fabric and pushed upwardly behind the same and permanently secured on the strengthening-web, said hooks being located on the inner side of and on each side of the garment.

698,088. SWITCHBOARD APPARATUS. WILLIAM MEYER, Chicago, Ill., assignor to the Greengard-Carlson Telephone Manufacturing Company, Chicago, Ill., a corporation of Illinois. Filed Oct. 16, 1901. Serial No. 73,195. (No model.)

Claim.—1. The combination with a bank of incandescent lamps, of a framework for mounting said lamps, a cover-plate for said lamps, provided with apertures registering with the said lamps, said apertures in said cover-plate, and means for removably securing said cover-plate to said framework, substantially as described.

2. The combination with a bank of incandescent lamps, of a framework for mounting said lamps, contact-springs provided in said framework, a cover-plate for said lamps provided with apertures registering with the said lamps, said apertures in said cover-plate, and means for removably securing said cover-plate to said framework, substantially as described.

3. The combination with a bank of incandescent lamps, of a framework for mounting said lamps, contact-springs provided in said framework, a cover-plate for said lamps provided with apertures registering with the said lamps, said apertures in said cover-plate, and spring-clamps for securing said cover-plate to said framework, substantially as described.

4. The combination with a bank of lamps, of a framework wherein said lamps may be mounted, springs for effecting electrical contact with said lamps, the framework for said lamps comprising a front plate provided with holes wherein the lamps may be mounted at one end, a cover-plate provided with apertures registering with said holes, said apertures having inclined surfaces, said apertures being provided with a spring for impinging against said inclined surfaces, and spring-clamps for removably securing said cover-plate to said framework, substantially as described.

5. The combination with a bank of lamps, of a framework wherein said lamps may be mounted, springs for effecting electrical contact with said lamps, the framework for said lamps comprising a front plate provided with holes wherein the lamps may be secured at one end, a cover-plate provided with apertures registering with said holes, said apertures having inclined surfaces, said apertures being provided with a spring for impinging against said inclined surfaces, and spring-clamps for removably securing said cover-plate to said framework, substantially as described.

6. The combination with a bank of lamps, of a framework wherein said lamps may be mounted, springs for effecting electrical contact with said lamps, the framework for said lamps comprising a front plate pro-

vided with holes wherein the lamps may be secured at one end, a cover-plate provided with apertures registering with said holes, said apertures having inclined surfaces, said apertures being provided with a spring for impinging against said inclined surfaces, a spring for holding the apertures in place, and spring-clamps for removably securing said cover-plate to said framework, substantially as described.

7. A cover-plate for mounting lamps in front of a bank of lamps, comprising a plate provided with apertures having inclined surfaces, said apertures being provided in said apertures impinging against said inclined surfaces, a spring for securing the apertures in place within the strip, and spring-clamps provided upon said strip, substantially as described.

8. A cover-plate for mounting lamps in front of a bank of lamps, comprising a plate provided with apertures having inclined surfaces, said apertures being provided in said apertures, and spring-clamps provided upon said strip, substantially as described.

698,089. PROCESS OF MAKING PLATES FOR STORAGE BATTERIES. ARTHUR MEYER, Paris, France. Filed Dec. 2, 1900. Serial No. 20,000. (No specimen.)

Claim.—1. The process of producing electrodes for storage batteries consisting in forcing a disintegrated active mass through a die-plate to form the mass into hollow sticks or tubes, placing these hollow sticks or tubes in a suitable mold, running metal into the mold which conducts the metal into the bases of the hollow sticks or tubes, that portion of the metal remaining in the mold constituting a frame integral with the metal cores received in the bases of the hollow sticks or tubes.

2. The process of producing electrodes for storage batteries consisting in forcing an active disintegrated mass through a die-plate from which it emerges in the form of hollow sticks or tubes of suitable contour, placing the hollow sticks or tubes in any desirable position with relation to one another, running field metal into the bases of the hollow sticks or tubes to form cores therefor, the field metal remaining outside of the bases of the hollow sticks and connected with the cores thereof formed into a frame integral with the cores in the bases of the hollow sticks or tubes.

3. The improved process of manufacturing electrodes for storage batteries which consists in forcing a disintegrated active mass through a suitable die-plate to produce sticks, coating the sticks with a chemical compound containing a pulverulent material and subsequently dissolving the pulverulent material whereby the necessary porosity is given the stick.

4. The improved process of producing electrodes for storage batteries consisting in forcing a disintegrated active mass through a die-plate from which it emerges in the form of hollow sticks or tubes, placing the hollow sticks or tubes in a mold running field metal into the mold, the metal being permitted to enter the bases of the hollow sticks or tubes to form cores therefor, the metal remaining in the mold connected to the cores of the hollow sticks or tubes being formed into a frame integral with the cores, coating the plates thus formed with varnish and subsequently giving the varnish the necessary porosity whereby the field may gain access to the active material.

5. A method or process of producing electrodes for storage batteries, consisting, first, in forcing a disintegrated active mass through means from which it emerges in the form of hollow sticks or tubes of suitable contour, second, in placing such sticks or tubes in a suitable mold in any desired design, third, in running any suitable metal into the bases of the hollow sticks or tubes to form cores therefor, the metal remaining in the mold having the form of a frame which is integral with the cores of the hollow sticks or tubes, fourth, in coating the plates with any suitable non-conducting covering and fifth, in giving each coating only, the necessary porosity.

698,044.

698,045. KNITTING-MACHINE. JAMES J. O'BRIEN, Boston, Mass.
Filed Oct. 4, 1900. Serial No. 32,310. (No model.)

Claim.—1. In a circular-knitting machine adapted for circular and reciprocating knitting, the combination with the cam-cylinder of a reinforcing-thread guide outside of said cylinder to contain a reinforcing-thread and deliver it to the needles and the fabric, of a take-up located below the top of the needles and acting on said reinforcing-thread when the latter is being knitted across after course into the fabric.

2. In a knitting-machine, the combination with a series of needles and a cam-cylinder capable of being rotated and reciprocated, a reinforcing-thread guide outside of said cylinder, means to put the delivery end of said thread-guide automatically in position to deliver its thread to the needles to be knitted into the fabric with the usual main thread during reciprocating knitting, of means to automatically turn the delivery end of the thread-guide for the reinforcing-thread into position in which said thread-guide will hold its thread in the needles to be taken and knitted with the main thread, said thread-guide in its inoperative position, however, permitting the reinforcing-thread to be drawn through it as the knitting progresses, thus leaving the reinforcing-thread always connected with the fabric, thereby avoiding kinks and other irregularities which result in breaking off the thread and damaging the work, and a take-up adjacent the reinforcing-thread guide to act upon the part of said reinforcing-thread passing through said guide and take-up being below the knitting-line.

3. In a circular-knitting machine adapted for circular and reciprocating knitting, a cam-cylinder, means to retain a cap or bobbin of reinforcing-thread, a reinforcing-thread guide to present said thread to the needles in knitting, means for changing the position of said reinforcing-thread guide with relation to the main-thread guide at alternate strokes to

thereby enable said reinforcing-thread guide to deliver its thread to the needles throughout reciprocating knitting.

4. In a circular-knitting machine adapted for circular and reciprocating knitting, the combination with the cam-cylinder, of a controller, and a reinforcing-thread guide having a spring-operated pin and cooperating with said controller, the latter effecting a change of position of the thread-guide between successive strokes in reciprocating knitting that said thread-guide may deliver its thread continuously to the needles throughout reciprocating knitting.

5. In a circular-knitting machine adapted for circular and reciprocating knitting, a cam-cylinder having a support for the reinforcing-thread, a reinforcing-thread guide movable with said cam-cylinder, means to turn said thread-guide toward the main-thread guide during each alternate stroke of reciprocating knitting, and a take-up acting on said reinforcing-thread.

6. In a circular-knitting machine adapted for circular and reciprocating knitting, the combination with the cam-cylinder, and a reinforcing-thread guide to contain a reinforcing-thread and to deliver it to the fabric being knitted together with the main thread, of a tension device acting upon said reinforcing-thread, and a take-up contained on said thread between said tension device and the delivery end of said thread-guide.

7. In a circular-knitting machine adapted for circular and reciprocating knitting, the combination with the cam-cylinder of a slide connected frictionally therewith and movable independently thereof and containing a main-thread guide, of a reinforcing-thread guide movable with said slide and containing a reinforcing-thread, and a take-up located below the knitting-line also movable with said slide and cam-cylinder, said take-up acting continuously on the reinforcing-thread.

8. In a circular-knitting machine adapted for circular and reciprocating knitting, the combination with the cam-cylinder of a slide connected frictionally therewith, of a reinforcing-thread guide movable with said slide and containing a reinforcing-thread, which is guided and delivered direct to the needles, a take-up also movable with said slide and acting continuously on the reinforcing-thread, and means to guide the take-up in its movements due to the stick in said reinforcing-thread.

9. In a circular-knitting machine adapted for circular and for reciprocating knitting, a series of needles, a cam-cylinder, a main-thread guide, and a reinforcing-thread guide partaking of the movements of the cam-cylinder in circular and in reciprocating knitting, a take-up cooperating with the reinforcing-thread, and means to cause said reinforcing-thread to be put into its operative position during a part of each course of knitting while the cam-cylinder is being moved in the direction of circular knitting and to change its position on reverse movement thereof.

10. In a circular-knitting machine adapted for circular and reciprocating knitting, the combination with the cam-cylinder having a reinforcing-thread guide outside of said cylinder to contain a reinforcing-thread, of means to move said thread-guide that it may deliver its thread to the needles when the fabric is to be thickened, and put said reinforcing-thread guide in its inoperative position when it is desired to omit the reinforcing-thread, said thread-guide holding the thread unbroken between itself and the fabric, and a take-up acting as a weight on the reinforcing-thread and occupying a position below the knitting-point.

698,046. ELECTRIC LAMP. HENRY J. LAMP, New York, N. Y. Filed Nov. 14, 1897. Renewed Mar. 14, 1900. Serial No. 32,311. (No model.)

Claim.—1. A feeding mechanism comprising a solenoid and core, a pair of relative clutch members, brackets rigidly secured to the core for supporting the same, said clutch members having lateral movement relatively to said brackets, an abutment carried by the brackets for one of said clutch members, the other of said clutch members being adapted to have lateral movement, a pressure adapted to act on the last-mentioned clutch member and means for regulating the action of said pressure upon said clutch member, substantially as described.

2. A feeding mechanism comprising a solenoid and core, a pair of relative clutch members, brackets rigidly carried by the core to support said clutch members so they may have lateral movement, an abutment carried by the brackets for one of said members, a pressure to act on the other of said clutch members, and means for regulating the action of said pressure upon said member, substantially as described.

3. A feeding mechanism comprising a solenoid and core, brackets rigidly carried by the core, a pair of grooved relative clutch members supported by the brackets, an abutment carried by the core for one of said members, one of said clutch members held from lateral movement, being adapted to have lateral movement, a lever to act upon said movable member, said lever having a spring-actuated arm, and an abutment for said arm, substantially as described.

4. A feeding mechanism comprising a bar, brackets depending therefrom, relative clutch members journaled on said brackets, one of said members

been adapted to have lateral movement, a lever pivotedly carried by one of said brackets to act on said movable clutch member, and an abutment for said lever, substantially as described.

5. A feeding mechanism comprising a bar, brackets depending therefrom, relative grooved clutch members journaled on said brackets, to have lateral movement relatively thereto, an abutment for one of said clutch members, the other clutch member being adapted to have lateral movement, a pressure to act upon said movable clutch member, said pressure having a spring-actuated arm, and an abutment for said arm, substantially as described.

6. The combination of a pair of solenoids and their cores with a bar carried by said cores, a pair of clutch members carried by said bar, one of said clutch members being adapted to have lateral movement, a pressure to act upon said movable clutch member, to move bodily toward a carbon, an independent abutment for the pressure, and means for regulating the pressure of said pressure upon said clutch member, substantially as described.

7. The combination of a pair of solenoids and their cores with a bar carried by said cores, a pair of grooved relative clutch members carried by said bar, an abutment for one of said clutch members, the other clutch member being adapted to have lateral movement bodily toward a carbon, a lever to act on said movable clutch member, said lever having a spring-actuated arm, and an abutment independent of the core for said arm, substantially as described.

8. A feeding mechanism comprising a pair of brackets having laterally-extending slots or openings, means for supporting said brackets, a pair of clutch members having supports located in said slots or openings to travel laterally therein, an abutment for one of said clutch members, a pressure to act with the other clutch member, and an abutment to act with said pressure, substantially as described.

9. A feeding mechanism comprising a bar 10, a pair of brackets depending therefrom, said brackets having laterally-extending slots or openings, a pair of relative clutch members having their pivots journaled in said slots or openings, an abutment for one of said clutch members, a pressure to act upon the other clutch member, and an abutment for the said pressure, substantially as described.

10. The combination of a cover for a globe having an opening for the passage of a carbon, and a tube having openings in opposite sides, with a clutch device comprising a pair of clutch members that are adapted to engage later said opening in the tube to act upon the carbon, one of said clutch members being laterally movable, a pressure to act with said movable clutch member, means for supporting said clutch members, and an abutment for said pressure, substantially as described.

11. The combination with a pair of solenoids and their cores, and carbon-feeding devices connected with said cores, of a yoke connected with said cores, said yoke having a spring-operated lever acting on said yoke against the weight of the cores and feeding devices, substantially as described.

12. The combination with a pair of solenoids and their cores, and carbon-feeding devices connected with said cores, of a yoke connected with said cores, and a spring-operated lever extending beneath said yoke and adapted to act thereon, and a dash-pot connected with said lever, substantially as described.

13. In an auto-tung the combination of a frame, a pair of solenoids carried thereby, cores for said solenoids, carbon-feeding devices connected with said cores, a yoke also connected with said cores, a support carried by said frame, a spring-operated lever pivoted to said support and extending beneath said yoke to act thereon, and a dash-pot carried by said frame and connected with said lever, substantially as described.

698,047. FIRE-ALARM. JOHN A. GLASS, Minneapolis, Minn.
Filed Jan. 15, 1901. Serial No. 62,322. (No model.)

Claim.—1. A device of the character described involving a dial having a dial and a crystal spaced apart, the latter outward of the former, in combination with a vibrating pointer having a spindle which projects axially through said dial, an adjustable electrode mounted to oscillate in the space between said dial and crystal and provided with a stem which works outward through said crystal approximately at the axis thereof, and a finger-piece secured to the outwardly-projected end of the stem of said electrode, and an electric circuit including said pointer and said electrode and involving an element which is actuated by the closing of the circuit between said pointer and electrode, substantially as described.

2. A device of the character described involving a dial and a crystal spaced apart, the latter outward of the former, in combination with a vibrating pointer having a spindle which projects axially through said dial a pair of independently-movable electrodes cooperating with said pointer and working in the space between said dial and said crystal and provided with stem portions which work outward through said crystal at other points on, but approximately at the axis of, said crystal, finger-pieces on the outer ends of the stems of said electrodes and an electric circuit including said pointer and said two electrodes and involving one or more elements which are actuated by the closing of the circuit between said pointer and either of said electrodes, substantially as described.

3. The combination with the case 1, dial 2, crystal 3 and thermally-actuated pointer 4, of the insulating-plate 5 extending through the central portion of said crystal 3, the electrodes 7, 7', pivoted in said plate 5, provided at their inner ends with contact-fingers 8 and at their outer ends with the crystal-engaging spring-coilings 9, a pair of balls, circuit connections from said balls to said pointer, and independent circuit connections from said balls to the said two electrodes, substantially as described.

698,048. SHUTTLE-BLOCK. PHILIP S. GANNON, Detroit, Mich. Filed Nov. 17, 1900. Serial No. 62,323. (No model.)

Claim.—1. In computing-mechanism of the class described, the combination of the price-beam and connecting-block relatively movable and a part with which the connecting-block cooperates at its lower extremity, said connecting-block consisting of the lower member, the upper frame, the links, and the movable block provided with means for engaging the beam, said links arranged to lift the movable block, substantially as described.

2. In computing-mechanism of the class described, the connecting-block consisting of the lower member, the frame, the movable member arranged to engage the beam and links connecting the lower member and the movable member and arranged to support the load from the lower member in weighing and to lift the movable member out of engagement with the beam to put the block in condition to be moved, substantially as described.

3. In said construction, the head-block and beam relatively mov-

able and a part with which the connecting-block cooperates at its lower extremity, said head-block including in its construction a frame having a slidable engagement with the beam and a movable member located above the frame and beam and arranged to fit down into engagement with the beam, by the weight of the head and the links engaged with said movable member and arranged to lift the same, substantially as described.

4. In said construction, the combination of the prior-beam provided with notches upon its upper edge and a head-block consisting of a frame having a slidable engagement with the beam, the movable member above the frame provided with centering-points, and the links having pivotal engagement with the movable member whereby the centering-points of said movable member are forced into engagement at the weighing-point with the beam when the head is thrown upon the links, substantially as described.

5. In said construction, the beam and head-block relatively movable, said head-block provided with a pair of rollers above the beam and a pair of rollers below the beam, the links and an element below the head-block capable of vertical movement and provided with an upstanding finger arranged to engage with the head-block between the lower pair of rollers, substantially as described.

6. In said construction, the beam, the connecting-block and the standing frame B, said connecting-block consisting of the head-block having two points of contact on the under side of the beam, the links and a member having a slidable engagement with the frame B provided with an upstanding finger arranged to engage the head-block between the two points of contact with the beam, substantially as described.

7. In said construction the beam and head-block relatively movable said head-block having two points of contact on the under side of the beam the links and a lower member provided with an upstanding finger arranged to engage the head-block between the two points of contact with the beam, substantially as described.

8. In said construction, the combination of the prior-beam, the head-block, the links, the frame B and a movable member on the upper edge of the frame provided with a finger arranged to engage with the head-block to cause said movable member and head-block to be moved together one by the other, substantially as described.

9. The head-block provided with a movable block arranged to engage the beam at two points, links suspended from said movable block to support the head and for lifting said block independent of the frame of the head-block to clear all points of engagement with the beam, substantially as described.

10. The head-block provided with a movable block arranged to engage the beam at two points, links suspended from said movable block to support the head and lift the block, and means for guiding the movable block to cause it to clear all points of engagement with the beam, substantially as described.

698,049. GUY-CARRIAGE. HENRY F. GUY, New York, N. Y. Filed May 21, 1898. Serial No. 961,200. (No model.)

Claim.—1. The combination in a gun-carriage of a pair of hollow wheels which have their distal ends closed and their tires or tracks mutually extended, with a riding-platform having lateral extensions within the wheels and a posterior extension between the wheels for the attachment of a third wheel.

2. In a gun-carriage, the combination of a pair of hollow wheels, which have their distal ends closed and their tires or tracks mutually extended, a connecting-rod, and a platform with lateral extensions within the wheels and a posterior extension between the wheels for the attachment of a third wheel substantially as described.

3. In a gun-carriage, the combination of a pair of hollow wheels which have their distal ends closed and their tires or tracks mutually extended, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

4. In a gun-carriage, the combination of a pair of hollow wheels which have their distal ends closed and their tires or tracks mutually extended, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

4. In a gun-carriage, the combination of a pair of hollow wheels which have their distal ends closed and their tires or tracks mutually extended, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

5. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

6. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

7. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

8. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

9. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

10. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

11. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

12. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

13. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

14. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

15. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

16. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

17. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

18. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

19. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

20. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

21. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

22. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

23. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

24. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

25. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

26. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

27. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

28. In a gun-carriage, the combination of a pair of hollow wheels having their distal ends closed and their tires or tracks mutually extended for motor and man protection, an electrical or other motor protectively arranged within said wheel or wheels, a connecting-rod, a platform supported by said rods and having lateral extensions within the hollow of the wheels a posterior extension between the wheels for the attachment of a third wheel and an anterior extension between the wheels for the attachment of a third wheel, substantially as described.

metallic connecting elements and covering the said sections together, substantially as described.

2. In a tank, a bottom formed of separable sections having an upstanding flange, a wall composed of separable sections, the base of which are seated on the bottom, within the flange thereof, straps secured to the upper portions of said side sections and having their respective ends bolted together, and straps secured to said side sections and having their lower ends bolted, bearing on and bolted to the bottom, substantially as described.

3. A tank having a plurality of sections, straps embedded in them, and bolts connecting said straps together at the joints between the sections, whereby the latter are separable, substantially as described.

4. A tank having a plurality of sections, each embedded in the material of one of the wall-sections, and bolts connecting the ends of the hoop-sections together at the joints between the wall-sections, substantially as described.

5. A tank having separable wall-sections, and sectional hoop-sections embedded and covered therein, said hoop-sections having their ends bolted together and adapted to be engaged by means for clamping the wall-sections together, substantially as described.

6. In a tank, the combination of separable sections formed of latently plastic material, metallic connecting elements formed and embedded in said sections, the latter having recesses exposing the ends of said metallic connecting elements, and bolts engaging the exposed ends of said metallic connecting elements and securing the said sections together, substantially as described.

698,051. COMBINATION CRIB-BUSH AND MOP. PHILIP F. HAYES, New York, N. Y. Filed Jan. 17, 1900. Serial No. 961,200. (No model.)

Claim.—1. In a combined crib-bush and mop, the combination with a brush body or body, of a mop-piece secured to its lower front portion and projecting outwardly therefrom, a chest or piece secured to the upper surface of the said body and having at one of its ends an opening, and at its other end a series of openings, and a series of openings at the ends of the chest and the upper surface of the chest and resting at its lower edge on the upper surface of the mop-piece, substantially as described.

2. In a combined crib-bush and mop, the combination with a brush body or body, of a mop-piece secured longitudinally to its front lower portion and projecting outwardly therefrom, and having an opening near each of its ends, a reinforcing strip or piece secured to the lower surface of the mop-piece, a supporting-rod located on the lower surface of the mop-piece and having its ends upturned through the openings in said piece, a chest or piece secured to the upper surface of the brush-body and having at one of its ends an opening, and at its other end a series of openings, a spring secured to the front surface of the chest and connected at its ends to the supporting-rod for the mop-piece, and a reservoir-rod secured in the ends of the brush-body and to the upper surface of the chest and having its lower edge in contact with the mop-piece, substantially as described.

698,050. SEWING-MACHINE. BERNARD E. PLATTEN, Chicago, Ill. Filed Jan. 1, 1900. Serial No. 961,200. (No model.)

Claim.—1. A tank having a plurality of sections, metallic connecting elements embedded in said sections, the latter having recesses exposing the ends of said metallic connecting elements and projecting over said recesses, and bolts engaging the exposed ends of the

698,052. GUIDING ATTACHMENT FOR DOORS. WASHINGTON
E. C. FLAGG, Seattle, Wash. Filed May 22, 1901. Serial No. 68,998.
(No model.)

Claim.—1. The combination with a swinging door or the like and jamb; of means to guide the rear edge of said door relatively to the jamb.
2. The combination with a door or the like and its jamb, of a guiding device having its members located on the jamb and rear edge of the door and cooperating with each other to direct said edge relatively to the jamb and prevent binding.
3. The combination with a door or the like and jamb; of a guide comprising a base fixed to the back stile of the door and carrying a rearwardly-projecting nose and a recess in the jamb arranged to receive and coast with said nose.
4. The combination with a door or the like and jamb; of a guide comprising a base fixed to the rear edge of said door and having a rearwardly-projecting nose, a recess in said jamb arranged to receive said guide and a way in the nose cooperating with said recess to direct said door edge relatively to the jamb.
5. The combination with a door or the like and the jamb; of a guide comprising a base fixed to the rear edge of said door, an antifriction-roller carried thereby and forming a rearwardly-projecting nose, a recess in said jamb arranged to receive the nose and a way in said recess having opposite bearing-surfaces cooperating with said roller to direct said door edge relatively to the jamb.
6. The combination with a door or the like and jamb, of a guide formed with a base adapted for attachment to the rear edge of a door or the like having brackets, a vertically-disposed roller axially supported thereby, and a substantially L-shaped way adapted for attachment to the jamb and formed with an aperture in one flange and projecting bearing-surfaces at opposite edges thereof adapted for cooperative association with said roller to direct said door edge during primary opening and final closing movement thereof.

698,053. VENTILATING-JACK FOR LANTERNS. ABRAHAM P. FRANK, Indianapolis, Ind. Filed May 2, 1901. Serial No. 68,410. (No model.)

Claim.—1. In a ventilating-jack for lanterns, the combination with a cover adapted to close the upper end of a lantern-body, of a tubular main body having a series of openings leading therein near its upper end and openings leading from its lower end and inside the cover, a shell of less diameter than the body mounted therein and leading upwardly there-through, a second open-ended shell mounted within the first shell and extending therethrough, an annular plate or bell closing the lower end of the annular space between the two shells, openings leading to the interior of the first shell near its lower end, and an annular impervious plate connecting the upper end of the main body to the first shell.

2. In a ventilating-jack for lanterns, the combination with a cover adapted to close the upper end of a lantern-body, of a tubular main body having a series of openings leading therein near its upper end and openings leading from its lower end, a shell protecting the upper openings, a shell of less diameter than the body mounted therein and leading upwardly there-through and shell having openings leading to its interior near the lower end, a second open-ended shell mounted within the first shell and extending therethrough, an annular plate or bell closing the lower end of the annular space between the two shells, and an annular impervious plate connecting the upper end of the main body to the first shell.

3. In a ventilating-jack for lanterns, the combination with a cover adapted to close the upper end of a lantern-body, of a tubular main body having a series of openings leading therein near its upper end and openings leading from its lower end, an open-ended shell of less diameter than the body mounted therein and leading upwardly there-through, an impervious annular plate separating the upper end of the main body with the open-ended shell, a perforated cylindrical shell carried by the upper end of the main body, a bell mounted in said shell and extending over the internal shell, and a ventilating-cap covering the end of the perforated shell.

4. In a ventilating-jack for lanterns, the combination with a cover adapted to close the upper end of a lantern-body, of a tubular main body having a series of openings leading therein near its upper end and openings leading from its lower end, a shell of less diameter than the body mounted therein and leading upwardly there-through, an annular plate or bell closing the lower end of the annular space between the two shells, an annular impervious plate connecting the upper end of the main body to the first shell, a perforated cylindrical shell carried by the upper end of the main body, a bell mounted in said shell and extending over the internal shell, and a ventilating-cap covering the end of the perforated shell.

5. In a jack for lanterns, the combination with a cover adapted to close the upper end of a lantern-body, of a tubular main body having openings leading therein near its upper end and openings leading from the lower end, a shell of less diameter than the main body mounted in said body, a deflecting-ledge mounted to the lower end of said shell and having perforations extending therethrough, a bell supported by the lower end of said flange, a second shell of less diameter than the first shell mounted in said first shell and secured at its lower end to said bell, an impervious annular plate closing the upper end of the main body, a perforated shell mounted above said plate, a ventilating-cap covering said perforated shell, and a bell arranged above the upper ends of first and second shells.

6. In a ventilating-jack for lanterns, the combination with a cover adapted to close the upper end of a lantern-body, of a tubular main body having an outwardly-flared upper end and a shell flaring upper end and being perforated with a series of openings, and a series of openings leading from the lower end of the tubular main body inside the cover, a shell of less diameter than the body mounted therein and leading upwardly there-through, a second open-ended shell mounted within the first shell and extending therethrough, an annular plate or bell closing the lower end of the annular space between the two shells, openings leading to the interior of the first shell near its lower end, and an annular impervious plate connecting the upper end of the main body to the first shell.

7. In a ventilating-jack for lanterns, the combination with a cover adapted to close the upper end of a lantern-body, of a tubular main body having a series of openings leading therein near its upper end, the said openings being formed in an outwardly-flaring flange forming the upper end of the tubular main body, and the said main body having a series of openings leading from its lower end and inside the cover, an open-ended shell of less diameter than the body mounted therein and leading upwardly there-through, an impervious annular plate connecting the upper flaring end of the main body with the open-ended shell, a perforated cylindrical shell carried by the upper end of the main body, a bell mounted in said shell and extending over the internal shell, a ventilating-cap covering the end of the perforated shell, and a depending guard secured at its upper end to the upper end of the flaring portion of the main body and extending downward as to overhang the openings through said flaring end of the main body, substantially as described.

698,054. HAIR-CLIPPER. CHARLES H. REHMAN, Haverhill, N. Y. Filed Aug. 10, 1901. Serial No. 71,568. (No model.)

Claim.—1. A hair-clipper, consisting of a lower comb-plate, an upper comb-plate, a cap-plate, said upper comb-plate being guided between the lower comb-plate and cap-plate, and clamping-covers passing through the cap-plate and upper comb-plate into the lower comb-plate, said clamping-covers being provided with coiled chains engaging tapering holes in

the cap-plate, and lower threaded ends engaging threaded openings in the lower comb-plate, substantially as set forth.

2. A hair-clipper, consisting of a lower comb-plate provided with threaded holes, an upper comb-plate guided on said lower comb-plate and provided with elongated slots, a cap-plate provided with tapering holes in alignment with the threaded holes of the bottom plate, and clamping-covers, the cheeks of which are coiledly tapering and threaded at their lower cylindrical ends, so as to fit into the tapering openings of the cap-plate and threaded openings of the lower comb-plate, substantially as set forth.

3. A hair-clipper, consisting of a lower comb-plate, an upper comb-plate, means for reciprocating the same on the lower comb-plate, a cap-plate bearing on the upper comb-plate, and provided with openings, and clamping-covers passing through said cap-plate and clamping on their lower ends into the lower comb-plate, said openings and the cheeks of said covers having a gradual taper extending through said cap-plate, substantially as set forth.

698,055. TELEPHONE INSTRUMENT. BARRY H. REYER, Chicago, Ill., assignor to the Western Electric Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Apr. 1, 1901. Serial No. 68,928. (No model.)

Claim.—1. In a telephone, the combination with a telephone-casing, of a diaphragm rotatably secured upon the casing, and manually-operated means located within the casing and operable from the exterior thereof, whereby the adjustment of the diaphragm may be locked, substantially as described.

2. In a telephone, the combination with the casing thereof, of a diaphragm having threaded engagement with its mounting or support, a locking-cam block having engagement with one of the parts having the said threaded engagement, and an eccentrically-mounted cam-pin to force the cam-block into and out of engagement with one of the said portions having threaded engagement, substantially as described.

3. In a telephone, the combination with the casing thereof, of a diaphragm having threaded engagement with its mounting or support, a locking-cam block having engagement with one of the parts having the said threaded engagement, and an eccentrically-mounted cam-pin to force the cam-block into and out of engagement with one of the said portions having threaded engagement, the said pin being provided with means extending through the casing of the instrument to secure its operation from without the instrument-casing, substantially as described.

4. In a telephone, the combination with the casing thereof, formed in two parts having threaded engagement, of a diaphragm provided upon one of the parts, and manually-operated means within the casing for locking the two parts together after one has been rotated upon the other to secure the desired adjustment of the diaphragm, the said means being accessible from the exterior of the casing, substantially as described.

5. In a telephone, the combination with the casing thereof, formed in two parts having threaded engagement, of a diaphragm provided upon one of the parts, a cam-block within the casing, an eccentric cam-pin also within the casing and accessible from the exterior thereof and having engagement with the said cam-block, and means provided upon one of the portions of the casing and adapted for engagement with the said cam-block, the said casing being provided with a slot between the said cam whereby the cam-block is engaging the said slot and secure binding engagement of the casing upon each side of the slot and secure binding engagement between the threaded portions of the casing, substantially as described.

6. In a telephone, the combination with the casing thereof, formed in two parts having threaded engagement, of a diaphragm provided upon one of the parts, and cam mechanism within the casing for locking the two parts together after one has been rotated upon the other to secure the desired adjustment of the diaphragm, the said cam mechanism being accessible from the exterior of the casing, substantially as described.

698,056. SHIRT-HOLDER. VALERIE F. REYER, Minneapolis, Minn. Filed Aug. 20, 1901. Serial No. 73,028. (No model.)

Claim.—A shirt-supporter comprising the flexible cord 2 provided at one end with the snap-hook 3 of such size that it may be snapped around said cord 2, the ring 4 at the other end of said cord 2 chains 10 attached to said ring 4, the ring 9 connecting the free ends of said chain, the spring-champ 5 connected to said ring 9 and provided at the free ends of its prongs with the head 6 with pads 7, and the hook 8 sliding on the prongs of said clamp to close the jaws of the same, substantially as described.

698,057. CAN HOLDER OR JACKET FOR CAN-CAPPING MACHINES. GEORGE H. REHMAN and GEORGE G. MILLER, Burlington, Ohio. Filed Aug. 20, 1901. Serial No. 73,029. (No model.)

Claim.—1. An attachment for can-capping machines consisting of a can holder or jacket in the form of a hollow body having an external shape and size corresponding to that of the largest can of a type to be fed to the machine and capable of snugly receiving a smaller can, the interior of the body corresponding in shape thereto, and the top of the body having an opening to expose the top of a can contained therein to the capping apparatus of the machine.

2. A can jacket or holder for can-capping machines, embodying a hollow body having an open end for the reception of a can, and to expose the cap and throat, the external diameter of the holder or jacket being equal to the largest standard size of can, and its inner diameter corresponding to that of a smaller size of can.

3. A can jacket or holder for can-capping machines, embodying a hollow body having an open end for the reception of a can, and to expose the cap and throat, the external diameter of the holder or jacket being equal to the largest standard size of can, and its inner diameter corresponding to that of a smaller size of can, and a can-support within the jacket and located above the bottom thereof.

4. A can jacket or holder for can-capping machines, comprising a hollow open-ended body having an external diameter equal to that of the largest standard size of can, and its internal diameter being equal to a smaller size of can, and a plurality of laterally-directed projections carried by the inner side of the holder and slightly above the lower open end thereof to provide means for supporting a can within the jacket or holder.

5. A can jacket or holder for can-capping machines, comprising an outer shell, an inner shell, opposite rims or bands connecting corresponding ends of the shells, and an inner can-support adjacent to the lower end of the body.

698,058. MILL AND BOLSTER CONSTRUCTION FOR STEEL CARB. RALPH V. BARR, Johnstown, Pa. Filed Jan. 24, 1902. Serial No. 73,198. (No model.)

Claim.—1. In mill and bolster construction for steel carb, the com-

bination of a center sill reduced in height at the ends to that of the draft-sill by cutting away the bottom for a sufficient distance to clear the truck. draft-sills abutting at their rear ends against the ends of the center sill, a center diaphragm secured between the draft and center sills at their juncture, a body-bolter secured at its inner ends to said draft and center sills, and top and bottom connection-plugs tying the whole together.

2. Is a steel car, draft-sill composed of two Z-shaped bars having their upper horizontal flanges turned inward, and a center sill composed of two channels having their flanges turned toward each other and their bottoms cut away at the ends to reduce their height to that of the draft-sills, the ends of the draft and center sills being spliced above the trucks.

3. Is a steel car, draft-sill composed of two Z-shaped bars having their upper horizontal flanges turned inward, a center sill composed of two channels having their flanges turned toward each other and their bottoms cut away at their ends to reduce their height to that of the draft-sills, the ends of the draft and center sills being spliced above the trucks, and a body-bolter having its inner ends secured to the draft and center sills on each side of their point of juncture.

4. Is a steel car, draft-sill composed of two Z-shaped bars having their upper horizontal flanges turned inward, a center sill composed of two channels having their flanges turned toward each other and their bottoms cut away at the ends to reduce their height to that of the draft-sills, the ends of the draft and center sills being spliced above the trucks, and a center diaphragm composed of two channel-irons back to back and pressed apart at the center to receive the king-pin and secured to the draft and center sills on each side of the point of juncture.

5. Is a steel car, draft-sill composed of two Z-shaped bars having their upper horizontal flanges turned inward, a center sill composed of two channels having their flanges turned toward each other and their bottoms cut away at the ends to reduce their height to that of the draft-sills, the ends of the draft and center sills being spliced above the trucks, a body-bolter having its inner ends secured to the draft and center sills on each side of their point of juncture, and a center diaphragm composed of two channel-irons back to back and pressed apart at the center to receive the king-pin and secured to the draft and center sills on each side of their point of juncture.

698,059. DRAFT-EQUALIZER. WILLIAM SHULTZ, Aptington, Iowa. Filed Jan. 20, 1905. Serial No. 91,912. (No model.)

Claim.—1. In a draft-equalizing apparatus, the combination of an intermediately-fabricated draw-bar, the fabricum of which forms the point of application of the draft to a vehicle, a draft connection applied to one end of the draw-bar, a doubletree connected to the other end of the draw-bar and otherwise independent of the first-mentioned draft connection, and an equalizing device included in the connection between the doubletree and the draw-bar and forming the sole support for the doubletree.

2. In a draft-equalizing apparatus, the combination of an intermediately-fabricated draw-bar, the fabricum of which forms the point of application of the draft to a vehicle, a doubletree applied to one end of the draw-bar, a doubletree connected to the other end of the draw-bar and

otherwise independent of the doubletree, and an equalizing device included in the connection between the doubletree and the draw-bar and comprising a fabricum equalizing-bar having its free end connected to the adjacent end of the draw-bar, the doubletree being connected to an intermediate portion of the equalizing-bar, the latter forming the sole support for the doubletree.

3. The combination with a harvesting-machine, having a draft-pole located at one side thereof, of a draw-bar fabricated intermediately in rear of and centrally with respect to the cutting apparatus of the machine, a draft connection applied to one end of the draw-bar, an over-bar pivoted upon the draft-pole, a connection between the free end of the over-bar and the other end of the draw-bar, and a doubletree connected to an intermediate portion of the over-bar.

4. The combination with a harvesting-machine, having a draft-pole located at one side thereof, of a draw-bar fabricated intermediately in rear of and centrally with respect to the cutting apparatus of the machine, an outwardly-directed bracket carried by the pole, an over-bar pivoted at its outer end to the bracket and projected inwardly and transversely across the pole, a connection between the free end of the over-bar and the adjacent end of the draw-bar, a doubletree pivotedly connected to an intermediate portion of the over-bar, and a draft connection applied to the opposite end of the draw-bar, the said draft connection and the doubletree being located at opposite sides of the cutting apparatus of the machine, and the doubletree being projected at opposite sides of the pole.

5. The combination with a harvesting-machine, having a pair of over-bars located in rear of the cutting apparatus thereof, and a draft-pole located at one side of the machine, of a bracket extending between the two over-bars and located centrally in rear of the cutting apparatus, a draw-bar fabricated intermediately upon the bracket, a bracket carried by and projected laterally outward from the pole, an over-bar pivoted to the bracket and projected transversely inward across the pole, a connection between the free end of the over-bar and the adjacent end of the draw-bar, a doubletree connected to the intermediate portion of the over-bar and projected equally at opposite sides of the pole, and a draft connection applied to the opposite end of the draw-bar, said draft connection and the doubletree being located at opposite sides of the cutting apparatus.

6. In a draft-equalizing apparatus, the combination of an intermediately-fabricated draw-bar, a draft connection applied to one end thereof, an equalizing-bar fabricated at one end and having its free end connected to the other end of the draw-bar, and a doubletree connected to an intermediate portion of the over-bar.

7. In a draft-equalizing apparatus, the combination of a bracket comprising top and bottom members having lateral connections, a draw-bar fabricated intermediately between the members of the bracket, a draft connection applied to one end of the draw-bar, a shorter draft connection applied to the opposite end of the draw-bar, an over-bar having one end connected to the forward end of the latter draft connection and projected laterally outward therefrom, a supporting-bracket having the outer end of the over-bar pivoted thereto, and a doubletree pivotedly connected to the central portion of the over-bar.

8. In combination with a harvester, of a draw-bar fabricated in rear of the cutting apparatus thereof, and draft connections for the opposite ends of the draw-bar, said draft connections being arranged so as to lie on opposite sides of the cutting apparatus, and each of the draft connections having means for attaching the draft-animals thereto, one of the draft connections being mounted on the pole or tongue.

9. The combination with a harvester, of a draw-bar fabricated in rear of the cutting apparatus, and draft connections for the opposite ends of the draw-bar, said draft connections being arranged so as to lie on opposite sides of the cutting apparatus, and each of the draft connections having means for attaching the draft-animals thereto, one of the draft connections being mounted on the pole or tongue and having an equalizing device included therein.

10. The combination with a harvester, of a draw-bar fabricated in rear of the cutting apparatus thereof, and draft connections for the opposite ends of the draw-bar, said draft connections being arranged so as to lie on opposite sides of the cutting apparatus, and each of the draft connections having means for attaching the draft-animals thereto, one of the draft connections being mounted on the pole or tongue of the harvester and including a pivotal equalizing-bar, a doubletree connected thereto, and a connection between the pivotal equalizing-bar and the adjacent end of the draw-bar.

698,060. SUPPORTING-FRAME FOR THE CONSTRUCTION OF OPEN CYLINDRICAL CRATES. FRANK SUMNER, Chicago, Ill. Filed Sept. 8, 1905. Serial No. 29,167. (No model.)

Claim.—1. A device for the construction of open cylindrical crates comprising substantially end rings, longitudinal bars connecting the same

and inwardly-extending pins upon said longitudinal members adapted to position and secure the hoops of the crate in proper position relative to the longitudinal members thereof; substantially as described.

2. An apparatus for the construction of open cylindrical crates comprising substantially a frame of end rings connected by longitudinal bars, one of which may open for the removal of the crate and a bar adapted to extend longitudinally through the rings and to support said frame during the construction of the crate; substantially as described.

698,061. BARANA-SHIPPING CASE. FRANK SUMNER, Chicago, Ill. Filed Oct. 2, 1905. Serial No. 29,214. (No model.)

Claim.—1. The combination with a surrounding crate and a case hung within the same, having a circumferential seam and an intersecting longitudinal seam, of a cord passing inward on one side of the longitudinal seam, outward on the other side of the longitudinal seam about the crate, inward again on the other side of the circumferential seam, thence across the longitudinal seam and outward on the same side on the circumferential seam and secured to the crate so that the cord engages and supports all four corners of the case about the intersecting seams; substantially as described.

2. In a shipping-case, the combination with a surrounding crate, of a case hung within the same consisting of a cylindrical portion and a conical portion formed from a conical piece of material by moving the portions of the straight edge on opposite sides of the middle together, and the straight edge to the one end of the cylindrical portion; substantially as described.

3. In a banana-shipping case, the combination with a suitable crate, composed of longitudinal slats and connecting-hoops, of a case hung in said crate and securely fastened in place out of contact therewith, an outer bottom, X, fastened to the lower hoop and an outer covering suitably secured to the outside of the case, and insulating said case; substantially as described.

4. In a banana-shipping case, the combination with a suitable crate, composed of longitudinal slats and connecting-hoops, of a case hung within the said crate and securely fastened in place out of contact therewith, an outer bottom, X, fastened to the lower hoop and an outer covering suitably secured to the top and bottom hoops of the crate and insulating said case; substantially as described.

698,062. METHOD OF MANUFACTURING GAS. FRANK SUMNER, W. C. SUMNER, New York, N. Y., assignors to the United Coke & Gas Company, Charleston, W. Va., and Philadelphia, Pa., a Corporation of West Virginia. Filed Aug. 22, 1905. Serial No. 29,266. (No model.)

Claim.—1. The method of manufacturing gas which consists in subjecting carbonaceous material to dry distillation, separating the gas thus produced into two portions, extracting the illuminants from one divided portion and mixing said illuminants with the other portion in order to enrich it, treating another body of carbonaceous material to produce water-gas and mixing said water-gas with the enriched portion of the gas produced by distillation in order to increase its volume and diminish its percentage of carbonaceous impurities.

2. The method of manufacturing gas which consists in subjecting carbonaceous material to dry distillation, separating the gas thus produced into two portions, extracting the illuminants from one divided portion and mixing said illuminants with the other portion in order to enrich it, treating another body of carbonaceous material to produce water-gas and mixing said water-gas with the enriched portion of the gas produced by distillation in order to increase its volume and diminish its percentage of carbonaceous impurities.

3. The method of manufacturing gas which consists in subjecting carbonaceous material to dry distillation, separating the gas thus produced into two portions, extracting the illuminants from one divided portion and mixing said illuminants with the other portion in order to enrich it, treating another body of carbonaceous material alternately with blasts of air and steam to produce producer and water gas, mixing said water-gas with the enriched portion of the gas produced by distillation in order to increase its volume and diminish its percentage of carbonaceous impurities, mixing the producer-gas with a portion of the gas robbed of its illuminants and using said last-mentioned gases for the distillation of the carbonaceous material.

4. The method of manufacturing gas which consists in subjecting carbonaceous material to dry distillation to drive off its gases, separating the richer and poorer gases produced, treating the poorer portion of gas to extract its contained illuminants, mixing said extracted illuminants with the richer division of the gas to enrich it, treating another body of carbonaceous material for the manufacture of water-gas and mixing said water-gas with the enriched gas to increase its volume and diminish its percentage of contained carbonaceous compounds.

5. The method of manufacturing gas which consists in subjecting carbonaceous material to dry distillation to drive off its gases, separating the richer and poorer gases produced, treating the poorer portion of gas to extract its contained illuminants, mixing said extracted illuminants with the richer division of the gas to enrich it, treating another body of carbonaceous material with alternate blasts of air and steam for the manufacture of producer and water gas, mixing said water-gas with the enriched gas to increase its volume and diminish its percentage of contained carbonaceous compounds, mixing the producer-gas with the poorer division of the gas distilled, and using said last-mentioned mixture for the distillation of the carbonaceous material.

898,068. PLANT FOR MANUFACTURING GAS. FRANK W. C. SHAW, New York, N. Y., assignor to the United Gas & Oil Company, Charleston, W. Va., and Philadelphia, Pa., a Corporation of West Virginia. Filed Aug. 20, 1907. Serial No. 59,896. (No model.)

Claim.—1. A plant for manufacturing gas having in combination a series of externally-heated gas-retorts having gas-furnaces for heating them, two conduits, each connected to receive gas from one or more of the retorts, a connection from one of said conduits to the gas-furnaces and a connection from the other conduit to a gas-reservoir, a water-gas generator adapted to produce alternately water and producer gas, connections from said generator to the two conduits leading from the retorts and means as valves whereby the water-gas is directed into the reservoir and the producer-gas into the gas-furnaces.

2. A plant for manufacturing gas having in combination two or more externally-heated gas-retorts, two conduits, each connected to receive gas from one or more of the retorts, an apparatus for extracting illuminants connected to treat the gas passing through one of said conduits and to deliver the extracted illuminants to the other conduit, a water-gas generator and connections from said generator to the conduit carrying the enriched gas.

3. A plant for manufacturing gas having in combination two or more externally-heated gas-retorts having gas-furnaces for heating them, two conduits, each connected to receive gas from one or more of the retorts, an apparatus for extracting illuminants connected to treat the gas passing through one of said conduits and to deliver the extracted illuminants to the other conduit, a reservoir arranged to receive the gas treated for the extraction of illuminants, a water-gas generator adapted to produce alternately water and producer gas, connections from said generator to the producer-gas reservoir and to the enriched-gas conduit and valves for directing the gas through either connection at will.

4. A plant for manufacturing gas having in combination a series of closed externally-heated gas-retorts, two conduits leading from said retorts and means for connecting said conduits with each retort at will, apparatus for extracting illuminants from gas arranged to connect with one conduit so as to treat the gas passing through it and to connect with the other conduit to deliver the extracted illuminants therein in admixture with the gas passing through it and a water-gas generator connected to deliver water-gas into the conduit containing the enriched gas.

5. A plant for manufacturing gas having in combination a series of closed externally-heated gas-retorts, two conduits leading from said retorts and means for connecting said conduits with each retort at will, apparatus for extracting illuminants from gas arranged to connect with one conduit so as to treat the gas passing through it and to connect with the other conduit to deliver the extracted illuminants therein in admixture with the gas passing through it, a water-gas generator, a carbureting plant, and connections from the water-gas generator to the conduit containing the enriched gas both direct and through the carbureting plant.

6. A plant for manufacturing gas having in combination a series of closed externally-heated gas-retorts provided with gas-furnaces for heating them, two conduits for the gas produced in the retorts, means for connecting each retort with either conduit at will, apparatus for extracting illuminants from gas connected to treat the gas passing through one conduit and to deliver the extracted illuminants into the gas in the other conduit, a reservoir arranged to receive the gas robbed of its illuminants and connected to deliver gas to the gas-furnaces heating the retorts, a generator adapted to produce alternately water and producer gas, a connection from said generator to the rich-gas conduit, a second connection from said generator to the poor-gas reservoir and valves whereby the said connections can be opened or closed at will.

898,064. CUTTING MACHINES AND CUTTING-TABLE AND PATTERNS THEREFOR. GEORGE BURT, Amsterdam, N. Y., and BERNARD B. WYTHE, Chicago, Ill. Filed Mar. 12, 1901. Serial No. 61,893. (No model.)

Claim.—1. A cutting device having a base suitably supporting a cutter, and separate guiding legs or trunnions projecting downwardly from said base, and constructed to slide freely in curved grooves or channels, substantially as described.

2. A cutting-table or pattern having grooves or channels, in combination with a cutting device having separate guiding legs or trunnions constructed to slide freely in said curved grooves or channels, whereby the cutting can be guided in said grooves and follow a curved pattern, substantially as described.

3. A cutting-table or pattern having grooves or channels therein and means for locating the position of the fabric over said grooves, in combination with a cutter having separate guiding legs or trunnions constructed to slide freely in said curved grooves or channels, substantially as described.

4. A cutting-table or pattern having guiding grooves or channels representing different-sized garments, in combination with a cutter having separate guiding legs or trunnions constructed to slide freely in said curved grooves or channels, substantially as described.

5. A cutting-table or pattern having grooves or channels for guiding a cutter, and sliding indexes establishing the edge of the garments, substantially as described.

6. A cutting-table or pattern having grooves or channels therein for guiding a cutter, and indexes for locating the position of the fabric adapted to rest above said grooves or channels, in combination with a cutter arranged to coast with said grooves or channels, substantially as described.

898,065. DUST-BEATER. STEVE J. SMITH, Buffalo, N. Y. Filed July 8, 1907. Serial No. 62,991. (No model.)

Claim.—1. A dust-beater, having a beater-head comprising a frame and interwoven wire coils within the space bounded by said frame, said coils being supported on the latter, substantially as set forth.

2. A dust-beater, having a beater-head comprising a circular frame and concentric interwoven coils held within and supported by said frame, substantially as set forth.

3. A dust-beater, having a beater-head comprising a frame, a wire extending therefrom to the center thereof and having a ring or eye at its inner end, a series of concentric interwoven wire coils arranged within

the circular frame and having its outer coil secured to said frame, and its inner coil secured to said ring or eye, substantially as set forth.

4. The combination of the circular wire frame having outwardly-projecting continuations or extensions, a center wire extending from the center of the circular frame to a point beyond the same and having an eye or ring at its inner end and arranged concentrically with the circular frame, said outwardly-projecting continuations or extensions being twisted around said center wire and thereby forming the shank of the beater, a series of concentric interwoven wire coils arranged within the circular frame and supported by the same and the eye or ring on the center wire, and a handle secured to the wire forming the shank, substantially as set forth.

5. The combination of the circular wire frame having outwardly-projecting continuations or extensions, a center wire extending from the center of the circular frame to a point beyond the same and having an eye or ring formed at its inner end, said outwardly-projecting continuations or extensions being held to the center wire at or near said circular frame and having inwardly-projecting ends, and with the center wire forming the shank of the beater, wire connections between said eye or ring and the circular frame, a handle having a center longitudinal bore to receive the end of the center wire and longitudinal grooves having radial holes at their lower ends to receive the ends of the said extensions, and a ferrule secured to the inner end of the handle for holding the wires forming the shank therein, substantially as set forth.

898,066. SIDE-SEAMING MACHINE. CHARLES W. BARNER, Lancaster, N. H., assignor, by mesne assignments, to American Gun Company, Jersey City, N. J., a Corporation of New Jersey. Filed Feb. 15, 1901. Serial No. 43,999. (No model.)

Claim.—1. In a side-seaming machine the guide-plates d^1 carrying guide-rolls d^2 and provided with projecting ribs engaging transverse slots d^3 in the column A' and capable of lateral adjustment by means of said slots and bolts d^4 passing through the same, substantially as described.

2. In a side-seaming machine having a cam-forming mandrel b with a die-blank c loosely mounted therein and resting upon pins d , means for raising said knife-die and holding the same firmly in position during the formation of the seam, consisting of curved-rolls e mounted in a sliding beam f , and supporting said pins d , links g connecting said beam f with cam h attached to the rock-shaft i , segment-gear j also attached to said rock-shaft and engaged by rack k operated by the cam-roll l and cam m substantially as described.

3. In a side-seaming machine having a cam-forming mandrel b and wings d for wrapping a body-blank around said mandrel, means for holding said body-blank firmly against said mandrel during the formation of the seam, consisting of the bar e across d adapted to lift said bar

and mounted on sliding beam f links g connecting said beam f with cam h attached to rock-shaft i , segment-gear j also attached to said rock-shaft and engaged by rack k operated by cam-roll l and cam m substantially as described.

4. In a side-seaming machine having a die d^1 adapted to cooperate with a die c in forming a locked seam, means for regulating the alignment of said die d^1 with said die c consisting of parallel links d^2 pivoted to opposite ends of the link d^3 carrying said die d^1 and also at the opposite ends of said links d^2 to arms e attached to the rock-shaft i , one of said arms e having an adjustable eccentric-pin f working in a slot in the end of the corresponding link d^2 , by the adjustment of which eccentric-pin the distance between that end of the die d^1 and the die c is increased or diminished, substantially as described.

5. In a side-seaming machine having a toggle-die f adapted to cooperate with a knife-die c in forming a locked seam, means for regulating the alignment of said die f with said die c , consisting of parallel links f^1 pivoted at one end to the side of the frame f by which the die f is carried and connected at the other with the eccentric-shaft f^2 , in combination with the eccentric-shaft f^2 having at one end the adjustable eccentric f^3 , one of said links f^1 embracing the main body of said shaft and the other eccentric f^3 , by the adjustment of which eccentric the corresponding end of the die f is made to approach or recede from the die c and means for adjusting the relative positions of the frame f to the links f^1 to conform to changes of adjustment of each eccentric substantially as described.

6. In a side-seaming machine having a toggle-die f adapted to cooperate with a knife-die c in forming a locked seam, means for regulating the distance between said dies consisting of an eccentric-shaft f^2 inserted in a socket in the frame of the machine and capable of rotation and adjustment therein, the projecting portion of said shaft being eccentric to the portion in said socket, in combination with parallel links f^1 pivoted at one end to the frame f by which the die f is carried, the other end of said links being connected with the projecting portion of said eccentric-shaft f^2 substantially as described.

898,067. BASKET-PACKER. FRANKLIN E. SMITH, Wright, Cal. Filed Nov. 13, 1901. Serial No. 63,957. (No model.)

Claim.—1. A basket-packer, comprising a bottom having abutment flanges fixed in part, the remaining part being adjustable, to engage the bottom from that part only.

2. A basket-pusher, comprising a bottom having circumferential flanges fixed in part, the remaining part being adjustable, to expose the bottom from that part only, and means for locking said adjustable part in an upright position.

3. A basket-pusher comprising a bottom having circumferential low flanges, the flange on one side being adjustable to expose the bottom from that side, and a separate frame about said bottom having circumferential taller flanges, one of which, corresponding to the adjustable flange of the bottom, is also adjustable to expose the bottom from the same side.

4. A basket-pusher comprising a bottom having circumferential low flanges, the flange on one side being adjustable to expose the bottom from that side, a separate frame about said bottom having circumferential taller flanges, one of which, corresponding to the adjustable flange of the bottom, is also adjustable to expose the bottom from the same side, and means for locking both adjustable flanges in an upright position.

698,068. CHECK-LINE BUCKLE. DAVID G. P. SMEL, Louisville, Tex. Filed Jan. 24, 1902. Serial No. 91,112. (No model.)

Claim.—1. In a connector for branching lines, a buckle comprising a plate, loops at the ends of the plate and projected from one side thereof, a strap projected from the same side of the plate as the loops and cut inward therefrom, and an eye midway of the ends of the plate and projected from the opposite side thereof, and a clip pivotally connected to a side of the buckle by means of the said eye and adapted to swing from one end to the other of the buckle and toward and from the said buckle in either of its positions, substantially as specified.

2. In a connector for branching lines, a buckle comprising a plate and end loops, a second plate having an intermediate portion crimped to provide an eye, a strap connecting the two plates and projected from the same side of the buckle as the end loops and located inward therefrom a short distance, a clip, and a link pivotally connecting the clip with the eye of the buckle, substantially as set forth.

698,069. RAILWAY-TORPEDO. LEWIS G. BRUCE, Porton, Ohio. Filed Jan. 12, 1902. Serial No. 90,272. (No model.)

Claim.—1. A railway-torpedo having a holder closely embracing a portion of said torpedo and provided with parallel hooked arms projecting beyond the same, and spring holding devices carried by said arms.

2. A railway-torpedo having a holder projecting beyond the same and having parallel hooked arms, and spring arms pivotally mounted on said holder and having roll-engaging portions, as set forth.

3. A railway-torpedo comprising a torpedo, a holder secured thereto, a staff-engaging means on the torpedo, and spring-arms with hooks on the holder, as set forth.

4. The combination with a torpedo, of a cap thereon, a holder partially embracing said cap, spring-arms pivotally mounted on said arms, and staff-engaging means retained between the body of the torpedo and said cap, as set forth.

5. The combination with a railway-torpedo, of a cap thereon, staff-engaging means held between the torpedo and cap, and a holder retained by said cap, as set forth.

6. The combination with a torpedo and a cap, of staff-engaging means held between said torpedo and cap, a holder held by the cap and spring-arms on the holder and having spring-hooks, as set forth.

7. A railway-torpedo having a body portion, a cap, a holder retained between the body portion and cap with arms projecting beyond the torpedo and spring-arms on the holder having hooks to engage opposite sides of the rail, as set forth.

8. A torpedo comprising a torpedo proper, a cap portion embracing the same and cut away, a holder held between the cap and body and pro-

jecting through said cut-away portion, and spring-arms pivotally mounted on said holder and hooked at one end on the holder, as set forth.

698,070. WOOD PEG OR FASTENER FOR WOODEN RAILWAY-SLEEPERS OR TIMBER. FRANK STAM, Hursburg, Germany, assignor to Leo Stam, Hursburg, Germany. Filed Feb. 16, 1901. Serial No. 62,942. (No model.)

Claim.—1. A form of construction of the wood peg such as described which consists in the lower end being covered by a cap of fitted threads in order to protect it against moisture arising from the ground, substantially as heretofore described and shown.

2. A form of construction of the wood peg such as described which consists in the lower part of the closing-cap, which lower part projects into the longitudinal boring of the wood peg, being formed at its upper end into a funnel *f* which on the one hand prevents the rising of moisture from the ground, and on the other hand allows rain or snow water, which penetrates from above, to run away, substantially as heretofore described and shown.

698,071. APPARATUS FOR ROLLING CAR-AXLES. CHARLES STEINHA, Dapunta, Pa. Filed Mar. 4, 1902. Renewed Aug. 24, 1901. Serial No. 72,172. (No model.)

Claim.—The combination with the housing and a pair of lower rolls journaled therein, said rolls tapering from their center toward each end and carrying rollers at the end of the taper, of an eccentric roll having a flat face and of relatively greater diameter than the lower rolls, said eccentric roll being journaled in the housing above the dividing-line of the lower rolls and being tapered from its center toward each end, and segmental collars secured on said eccentric roll, said collars having one end terminating at the flat face of the roll, as and for the purpose specified.

698,072. PAVING-FLAG. JOSEF STEINMANN, Vienna, Austria-Hungary. Filed Oct. 1, 1900. Renewed Sept. 27, 1901. Serial No. 72,204. (No model.)

Claim.—1. Paving-flag, composed of a layer of concrete firmly connected by means of a strong pressure with an upper layer formed of a mixture of natural asphalt-cum, sulfur, carb-meal, iron oxide and granulated porphyry or any other kind of hard homogeneous stone, substantially as set forth.

2. The process of making the improved paving-flag, which consists in mixing natural asphalt-cum in a cold state with finely-divided sulfur, carb-meal iron oxide and granulated porphyry or other similar stone, heat-

ing the mixture to a temperature of 140° Celsius, maintaining the mixture at a temperature of 120° Celsius, then pouring the material into suitable molds containing a layer of maintained concrete, and finally submitting the molded flag to a strong pressure, the above materials being employed in about the proportions stated, substantially as set forth.

698,073. CLIPPER OR SHEARING-TOOL. JOHN E. SEWARD, Chicago, Ill. Filed Aug. 20, 1901. Serial No. 73,177. (No model.)

Claim.—1. In a clipper or shearing-tool, in combination with the vibrating cutter a main operating-lever and means for actuating it; a cleave or roller pivoted to said main operating-lever, and a secondary lever journaled in said cleave or roller and adapted to oscillate therein about the longitudinal axis thereof, and engaging and vibrating the cutter.

2. In a clipper or shearing-tool, in combination with the vibrating cutter a main operating-lever and means for actuating it; a secondary lever actuated by said main operating-lever, having pivotal connections therewith and a limited range of oscillation about a longitudinal axis, and of vertical movement with respect to said main operating-lever; the latter having a recess at its forward part with parallel vertical sides, and a bushing-plate having corresponding parallel vertical sides fitting closely between the vertical sides of said recess, said secondary lever being journaled and adapted to oscillate about the longitudinal axis of its stem in said bushing-plate.

3. In a clipper or shearing-tool, in combination with a vibrating cutter, the main operating-lever and means for actuating it; a secondary lever having pivotal connections with said main lever, with limited freedom of oscillation about a longitudinal axis, and of vertical movement in respect to said main lever, said secondary lever bearing on the vibrating cutter and constituting the medium by which the main lever actuates said cutter; a bushing-plate carried by the main operating-lever and having vertical movement with respect thereto, and restrained with respect to transverse movement; the secondary lever having a cylindrical stem journaled in the bushing-plate and adapted to oscillate therein; and a screw operating between said main lever and said secondary lever to adjust the secondary lever in vertical plane about its pivotal connection to the main operating-lever.

4. In a clipper or shearing-tool, in combination with the one or body having at the forward end the comb or fixed cutter, the vibrating cutter, the main operating-lever and means for actuating it; a secondary lever which at its forward end bears upon the vibrating cutter toward the opposite end of the latter; a supplemental finger pivoted at its rear end to said secondary lever, and at its forward end bearing upon the vibrating cutter intermediate the ends of the latter, and being forward of its pivotal connection to the secondary lever pivoted also to the main operating-lever, and having at its last-mentioned pivot limited freedom of oscillation about a longitudinal axis, and a bushing-plate on the stem of said secondary lever in which the latter is adapted to oscillate, said bushing-plate being mounted in the main operating-lever with capacity for vertical movement but restrained against lateral movement with respect to

said oscillating lever; and an adjusting-screw operating between the rear portion of said secondary lever and the operating-lever, to press the forward end of the secondary lever on the vibrating cutter.

5. In a clipper or shearing-tool, in combination with a cutter-operating lever, having an upwardly-facing bearing-surface, a plate against which said surface is pressed, having an aperture, and the oil holder and strainer, *M*, in said aperture having a flange at the upper end to retain the oil-straining material, and a shoulder, *M'*, stopping it on the plate.

6. In a clipper or shearing-tool, in combination with the cutter the main operating-lever and means for actuating it; a secondary lever actuated by said main operating-lever, and having a cylindrical stem; a bushing-plate on each stem, lodged in the main operating-lever and having capacity for vertical movement, but restrained against lateral movement in respect thereto; a pivot-pin extending through said bushing-plate and through said secondary lever and secured in the operating-lever, and connecting said three parts together; the aperture for said pin through the bushing-plate and through the secondary lever being vertically elongated to afford limited range of vertical movement and of oscillation about the axis of its stem to said secondary lever.

7. In a clipper or shearing-tool, an operating-lever and a secondary lever pivotally connected thereto, arranged at its forward end to bear upon the cutter; said operating-lever having a vertical threaded aperture back of the pivot of the secondary lever thereto and an opening into said threaded aperture at the forward side, the rear end of the secondary lever extending through said opening; a screw extending in said threaded aperture, and having at an intermediate point of its threaded extent a circumferential or annular groove which corresponds in position, when the screw is in operative relation with the other parts, with the opening in the forward side of said threaded aperture, the rear end of the secondary lever taking through said opening and engaging in the annular groove of the screw; whereby the latter serves to elevate the rear end of the lever to cause it to press at the forward end on the cutter.

698,074. MEAT-TENDER. EDWARD STONE, Ontario, Wis. Filed May 22, 1901. Serial No. 61,160. (No model.)

Claim.—1. A meat-tender comprising a base provided with a step, a reciprocating platform mounted on the base and provided with opposite step projections for limiting the movement of the platform, one of the step projections being movable and arranged to swing clear of the base to permit the platform to be detached, and a mangling member located above and cooperating with the platform and adapted to reciprocate the same, substantially as described.

2. A meat-tender, comprising a base, an intermediate fixed step device carried thereby, a reciprocating platform mounted upon the base, and provided with opposite step projections for contact with the fixed step device, one of the step projections being adjustable in clear of the fixed step device, and a swinging mangling member cooperating with the platform.

3. A meat-tender, comprising a base having an open top, and an intermediate cross-bar below the open top, a reciprocating platform mounted upon the top of the base, and provided with a pendant step projection extending below the top of the cross-bar to engage therewith at one end of the platform, and a laterally-swinging step-pin screw from the opposite undermost portion of the platform to engage the cross-bar at the opposite end of the platform and capable of being swung out of alignment with the cross-bar and a swinging mangling member cooperating with the top of the platform.

4. A meat-tender, comprising a base having an open top, a pair of rollers mounted transversely between the sides of the base and below the top thereof, the intermediate portions of the rollers being reduced, a cross-bar extending between the sides of the base and lying between the rollers, the intermediate portion of the top of the cross-bar being projected above the reduced portion of the rollers, a reciprocating platform mounted upon the enlarged portions of the rollers, and opposite pendant step projections carried by the platform, the lower ends of the projections lying below the top of the cross-bar and above the reduced portions of the rollers, whereby the cross-bar forms a fixed step for engagement by the step projections.

5. A meat-tender, comprising a base having an open top, and opposite inwardly-directed longitudinal flanges antifriction-rollers mounted transversely within the base and below the flanges, a reciprocating platform, having a pair of pendant longitudinal flanges resting upon the marginal edges of the terminal enlargements of the rollers, and provided in their outer sides with longitudinal grooves receiving the flanges of the base, and a swinging mangling member cooperating with the top of the platform.

6. A meat-tender comprising a base, a reciprocating platform mounted thereon, a standard rising from the base and provided with a tubular pivot extending over the platform, a mangling member mounted on the pivot and cooperating with the platform and having a tilting movement on the said pivot, out of line with its normal movement and a coiled spring housed within the tubular pivot and connecting the mangling member with its bearing, substantially as described.

7. A meat-tender, comprising a base, a reciprocating platform mounted thereon, a standard rising from the base and provided with a lateral pivot-rod overhanging the platform and provided with a longitudinal bore, there being an annular shoulder within the bore, a rocking mangling member cooperating with the platform and rotatably mounted upon the pivot-rod, a handle for the mangling member, an outwardly-movable belt passed through the bore of the pivot-rod and the mangling member, a coiled spring encircling the belt within the pivot-rod and bearing in opposite directions against the head of the belt and the shoulder within the bore of the pivot-rod, and a stop device upon the opposite end of the belt and lying against the mangling member, whereby the latter is capable of being laterally tilted upon its pivotal support.

8. In a meat-tender, the combination with a rotatable mangling member having a tapered pivotal opening, of a support therefor, having an externally-tapered pivot-pin to fit the tapered opening of the mangling member, the pin being provided with a longitudinal bore, and an inner marginal shoulder therein, a headed bolt passed through the pin and the mangling member with the head slidably received within the bore, a coiled spring about the bolt and bearing in opposite directions against the head thereof and the marginal shoulder within the pivot-pin, and a fastening applied to the opposite end of the bolt, whereby the mangling member may be tilted upon its pivotal support.

9. A meat-tender comprising a base, a standard having a pivot, a rocking mangling member mounted on the pivot and capable of tilting laterally, means for yieldingly engaging the mangling member, and a reciprocating platform located beneath the same, substantially as described.

698,075. **NECK-YOKER** JOHN H. STROCK, Weston, Pa. Filed Sept. 10, 1901. Serial No. 74,978. (No model.)

Claim.—1. The combination with a pole-tip having a flattened bulbous head, of a neck-yoker provided with means for securing it to said pole-tip, said means comprising a hollow body part having an opening adapted to receive between its walls the flat sides of the pole-tip, said opening being defined by opposite external flanges extending from end to end of the opening.

2. As a part of a neck-yoker, a socket member consisting of a hollow body part, conical and piece, and web, constituting walls of the body part and extending across the conical and piece.

3. As a part of a neck-yoker, a socket member consisting of a body part, conical and piece, web, and a flange extending from web to the other.

698,076. **ADJUSTABLE TROLLEY-SUPPORTER** THOMAS E. STROCK, Indianapolis, Ind. Filed Aug. 31, 1901. Serial No. 75,940. (No model.)

Claim.—1. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a current-conveyor and a horizontally-extending extensible arm pivoted to swing in a horizontal plane, and means on the free end of said arm whereby said current-conveyor is pivotally supported and maintained in position to contact with said side conductor.

2. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a current-conveyor, an extensible horizontally-extending arm pivoted to swing in a horizontal plane whereby said current-conveyor is supported and maintained in position to contact with said side conductor.

3. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a current-conveyor, and a horizontally-extending extensible arm pivotally mounted to swing in a horizontal plane, and situated at or near the forward end of the vehicle, and means on the free end of said arm whereby said current-conveyor is pivotally supported and maintained in position to contact with said side conductor.

4. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of the track, of a current-conveyor, a vertically-extending rotatable shaft, an arm extending horizontally from said vertical shaft and whereby said current-conveyor is supported and maintained in position to contact with said side conductor.

5. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a current-conveyor, a vertically-extending rotatable shaft, an extensible arm extending horizontally from the top end of said rotatable shaft, whereby said current-conveyor is supported and maintained in position to contact with said side conductor, and means for swinging and extending said arm and for locking same in position.

6. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a current-conveyor, a vertically-extending rotatable shaft, an extensible arm extending horizontally from the top end of said rotatable shaft whereby said current-conveyor is supported and maintained in position to contact with said side conductor, and independent means for swinging and extending said arm and for locking the same in position.

7. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a vertically-extending rotatable shaft, a horizontally-extending extensible arm rigidly secured at or near the top end of said vertical shaft, and a current-conveying means pivotally mounted on the free end of said extensible arm.

8. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a vertically-extending rotatable shaft, a horizontally-extending extensible arm rigidly secured at or near the top end of said vertical shaft, a current-conveying means pivotally mounted on the free end of said arm, and means for locking said arm in position.

9. The combination with a railroad-track, an electrically-propelled vehicle on said track and a current-conductor situated at one side of and above the plane of said track, of a vertically-extending rotatable shaft, a horizontally-extending extensible arm rigidly secured at or near the top end of said vertical shaft, a current-conveying means pivotally mounted on the free end of said arm, and independent means for extending said arm and for swinging the same into position.

10. The combination with a railroad-track, an electrically-propelled vehicle on said track and a current-conductor situated at one side of and above the plane of said track, of a vertically-extending rotatable shaft, a horizontally-extending extensible arm rigidly secured at or near the top end of said vertical shaft, a current-conveying means pivotally mounted on the free end of said arm, independent means for extending and swinging said arm and independent means for locking said swinging means and said arm extending means.

11. The combination with a railroad-track, an electrically-propelled vehicle on said track and a current-conductor situated at one side of and above the plane of the track, of a vertically-extending rotatable shaft, a horizontally-extending extensible arm rigidly secured to said vertical shaft at or near the top end thereof, a current-conveying means pivotally mounted

on the free end of said arm, independently-operated means situated on said vertical shaft for extending said arm and swinging the same, and independent means for locking said swinging and said extending means.

12. The combination with a railroad-track, an electrically-propelled vehicle on said track and a current-conductor situated at one side of and above the plane of said track, of a vertically-extending rotatable shaft, a horizontally-extending extensible arm rigidly secured to said vertical shaft at or near the top end thereof, a stop or floor bearing in which the bottom end of said vertical shaft is journaled and an upper bearing at or near the top end of said vertical shaft whereby the latter is steadied and held in vertical position.

13. The combination with a railroad-track, an electrically-propelled vehicle on said track, and a current-conductor situated at one side of and above the plane of said track, of a vertically-extending rotatable shaft, a horizontally-extending extensible arm rigidly secured to said vertical shaft at or near the top end thereof, means extending from the free end of said shaft to said vertical shaft, and an arm telescoping into said sleeve substantially as and for the purpose set forth.

14. The combination with a current-conductor and a current-conveyor, of a vertically-extending tubular shaft, a secondary vertically-extending shaft located in said tubular shaft, a horizontally-extending sleeve secured to said tubular shaft at or near the top end thereof, an extensible arm adapted to telescope into said sleeve, driving means connecting said arm and said interior shaft, and means extending from the interior of said tubular shaft whereby said interior vertical shaft is turned to traverse said arm.

15. The combination with a current-conductor and a current-conveyor of a vertically-extending tubular shaft, a secondary vertically-extending shaft located in said tubular shaft, a horizontally-extending sleeve secured to said tubular shaft at or near the top end thereof, an extensible arm adapted to telescope into said sleeve, a rack on one side of said arm, a pinion on said vertical shaft, and means extending from the interior of said tubular shaft to the exterior thereof for turning said interior shaft to manipulate the said extensible arm.

698,077. **HOLDING-BOARD** OLIVER C. SWINE, Watertown, N. Y. Filed Apr. 2, 1902. Serial No. 671,105. (No model.)

Claim.—1. The combination with a molding-board provided with a groove in its lower face, of a substantially U-shaped hook having one end or branch journaled in the molding-board and its opposite end or branch movable into and out of the groove, substantially as and for the purpose described.

2. The combination with a molding-board provided with a groove in its lower face, of a plate secured to the edge of the board in proximity to the groove, and a substantially U-shaped hook having one end or branch journaled in the plate and its opposite end or branch movable into and out of the groove, substantially as and for the purpose specified.

3. The combination with a molding-board, of a plate secured to the edge of the board and formed with a journal-opening, and a groove leading from said journal-opening and extending through the plate from front to rear, and a movable substantially U-shaped hook having one end or branch movable into engagement with a suitable support, and its opposite end or branch arranged in the journal-opening of the plate and provided with a shoulder normally engaged with the inner face of the plate and movable through said groove, substantially as and for the purpose set forth.

698,078. **HYDRAULIC** HENRY C. THOMAS, Boston, Mass. Filed Mar. 20, 1901. Serial No. 68,310. (No model.)

Claim.—1. In an eye-glass, in combination with the usual nose-guard, bow, lens, and holding-clamp, a washer F, having the angular perforation f placed vertically between and held rigidly by the projecting arm of the holding-clamp against the edge of the lens, and a holding-screw G having its termination g adapted to fit said perforation f to prevent said holding-screw G from turning; substantially as described.

2. In an eye-glass, in combination with the nose-guard, bow, lens, and usual holding-clamp, a spring-clamp having the part F angularly perforated at f, and having also the spring-arm e perforated at d', and a holding-screw G having its termination g adapted to fit the perforation f to prevent said holding-screw G from turning; substantially as described.

3. In an eye-glass, in combination with the usual nose-guard, bow, lens, and holding-clamp, a spring-clamp H, composed of the part F angularly perforated at f, and having also the extensions f' and the spring-arm e perforated at d', and the screw G having its termination g adapted to fit the perforation f to prevent said holding-screw G from turning; substantially as described.

698,079. **SALICYLATE OF SALTETYL GUININ**, Dr. HENNING THOMAS, Frankfurt-on-the-Main, Germany, assignor to Vereinigte Chemisch-Fabrikanten Rummel & Co., Carlshausen mit Dornschütz Hofung, Frankfurt-on-the-Main, Germany. Filed Jan. 4, 1902. Serial No. 68,481. (No specimens.)

Claim.—1. The herein-described new products prepared from one molecule of salicylic acid and one molecule of a salicylo-acid ester of di-phenyl alkylamine forming tasteless white crystals, insoluble in water, ether and ligroin but readily soluble in benzene, chloroform and hot alcohol.

2. The herein-described new product prepared from one molecule of salicylic acid and one molecule of salicylo-acid ester of quinin forming tasteless white crystals melting at 183° to 185° centrifugally insoluble in water, ether and ligroin, but readily soluble in benzene, chloroform and hot alcohol.

698,080. **SELF-OPENING POCKET-KNIFE** HENRY TILMAN, Be- light, Ark. Filed Nov. 12, 1901. Serial No. 68,048. (No model.)

Claim.—1. In a self-opening knife, the combination with a handle, and a back-spring having a chamber therein, of a covering for said chamber, a blade pivoted to the handle, a retractile spring located in the chamber of the back rib and anchored thereto and having the other end connected to the heel of the blade, and means for locking the blade.

2. In a self-opening knife, the combination with a handle, of a blade pivoted thereto, a spring locking-catch adapted to engage and lock the blade, and a spring-actuated unlatching-wedge adapted to engage against the locking-catch and withdraw it from engagement with the blade.

3. In a self-opening knife, the combination with a handle, of a blade pivoted thereto, a spring locking-catch adapted to engage and lock the blade, and a spring-actuated unlatching-slide having a slot and wedge, and a pin in the slot connected to the handle, said slide being disposed at an angle to the length of the locking-catch and the wedge being adapted to wipe against the locking-catch and withdraw it from engagement with the blade.

4. In a self-opening knife, the combination with a handle, of a spring-actuated blade pivoted thereto, provided with aperture in its heel arranged at opposite radial points, a spring carrying a pin on its free end to engage in said aperture and lock the blade in either closed or open position, and a slidable wedge to engage behind said spring to withdraw the pin from engagement.

5. A self-opening knife comprising a handle, a blade pivoted thereto having its heel provided with a locking-aperture, a back-spring, a retractile spring having one end secured to the back-spring and the other end secured to the back of the blade-heel, a spring carrying a pin on its free end to engage in the aperture in the heel of the blade and lock the blade closed, and a slide to engage the spring and withdraw the pin, whereby the retractile spring starts in force and opens the blade.

698,081. **HILLARDS-PILOW** WHEAT TUNNICLIFFE, Pasadena, Cal. Filed Dec. 28, 1901. Serial No. 68,078. (No model.)

Claim.—1. In a pillow, the combination with a frame comprising side beams, of reversible pillowcases disposed below the frame, means for effecting the relative endwise movement of the side beams, and means operated by the movement of the side beams for effecting the reversal of the individual cases.

2. In a pillow, the combination with a frame comprising side beams, of reversible pillowcases disposed below the frame, a reversing-lever for effecting the relative endwise adjustment of the side beams, and means

operated by the movement of the side beams for reversing the individual shares.

3. In a plow, the combination with a frame, of a plurality of reversible shares carried by the frame, and a reversing-lever arranged to simultaneously effect the adjustment of the frame members and the reversal of the several shares.

4. In a plow, the combination with a frame composed of pivotally-connected longitudinal and transverse frame members, of means for changing the relative positions of said members, means for locking the members in the positions to which they are moved, and reversible plows carried by certain of the members and operatively connected to certain other members, to effect the reversal of said plows when the frame members are adjusted.

5. In a plow, the combination with longitudinal frame members provided with rotary shares or standards, and shares carried thereby, of means for shifting said longitudinal frame members in opposite directions, and means for rotating the shares or standards through each relative movement.

6. In a plow, the combination with a frame comprising adjustable members, of rotary standards mounted in the frame, shares carried by the standards, and a reversing-lever operatively connected to the frame members and standards to adjust the members and rotate the standards simultaneously.

7. In a plow, the combination with a frame comprising side beams, of land-wheels carried by said beams, reversible plowshares disposed below the beams, means for effecting the relative and/or adjustment of the side beams to advance either of the land-wheels, and means for effecting the individual reversal of the shares.

8. In a plow, the combination with a frame comprising a pair of side beams, land-wheels carried by the side beams, and means for shifting the side beams longitudinally to effect the advance of one of the land-wheels, of rotary shares disposed below the frame, and means for automatically reversing the shares when the side beams are relatively adjusted.

9. In a plow, the combination with a frame comprising relatively adjustable side beams, and land-wheels movable independently of the beams, of reversible plowshares disposed below the frame, means for raising and lowering the land-wheels to effect the raising and lowering of the shares, means for effecting the relative adjustment of the side beams, and means for reversing the shares.

10. In a plow, the combination with a frame comprising a pair of relatively movable side beams, and connecting members, of land-wheels independently movable with the side beams, rotary standards carried by the side beams, shares mounted on the standards to effect the elevation and depression of the shares, and means for locking said parts in their adjusted positions.

11. In a plow, the combination with a frame comprising longitudinal and transverse frame members having pivotal connection, of plowshares disposed below the longitudinal frame members, and a reversing-lever connected to one of the transverse frame members and constituting means for effecting the adjustment of the frame.

12. In a plow, the combination with a frame comprising side beams, and transverse frame members pivotally connected to the side beams, of a reversing-lever extending from one of the transverse frame members and constituting means for adjusting the frame, rotary standards mounted in the side beams and provided with plowshares, and means for effecting a connection between a frame member and a standard to rotate the latter through the movement of said transverse member.

13. In a plow, the combination with a frame comprising side beams, and transverse frame members pivotally connected thereto, of rotary standards mounted in the side beams and provided with crank-arms, plowshares mounted in the standards, and means operatively connecting the crank-arms with a transverse frame member, whereby the standards will be rotated when said transverse member is shifted with respect to the side beams.

14. In a plow, the combination with side beams, and transverse frame members pivotally connected thereto and provided with arms, of

rotary standards mounted in the side beams and having crank-arms operatively connected with the arms of a transverse member, and shares mounted on the standards.

15. In a plow, the combination with side beams, and transverse members pivotally connected thereto, of rotary standards mounted in the side beams and provided with shares, a crank-arm mounted on each of the standards, arms projecting from the opposite ends of the transverse members and engaging the crank-arms of the standards, and a reversing-lever secured to the transverse member and extended rearwardly.

16. In a plow, the combination with side beams, and transverse frame members, of rotary standards mounted in the side beams, shares carried by the standards, means for effecting the rotation of the standards through the relative movement of the side beams, a reversing-lever extended rearwardly from one of the transverse frame members, and a hook-carried by another of the transverse frame members for the retention of the reversing-lever.

17. In a plow, the combination with a frame comprising side beams, and transverse members pivotally connected to the side beams, of shares disposed below the side beams, a draft-link pivotally connected at its opposite ends to the side beams, and a draw-bar detachably connected to the draft-link.

18. In a plow, the combination with side beams, transverse frame members, and shares, of means for adjusting the relative positions of the said members, a draft-link pivotally connected at its opposite ends to the side beams, a draw-bar detachably connected at its rear end to the draft-link, and an adjustable draft-lever disposed in advance of the draft-link and serving as a guide for the draw-bar.

19. In a plow, the combination with a standard provided with a shoulder, and a share, of a pair of bolts passed through the standard and share and provided with reduced portions, a heel-plate provided with key-slots for the reception of the bolts, and a wedge disposed between one end of the heel-plate and the shoulder of the standard.

698,083. PHOTOGRAPH. CHARLES W. VERNE, Toronto, Canada, assignor of one-half to Matthew Greenwell Fletcher Hamby, Toronto, Canada, and Margaret Hamby, Ottawa, Canada. Filed Oct. 21, 1901. Serial No. 79,686. (No model.)

Claim.—1. The combination with the frame, the arbor suitably journaled therein, the side rod forming one side of the frame, the sleeve longitudinally adjustable thereon, the recorder-arm secured at one end to the sleeve and suitably supported at the opposite end on the frame, the feed-arm suitably secured to the sleeve and provided with a nut having an arc-shaped recess threaded up as to engage with the screw-threaded end of the arbor and said nut being centrally pivoted in the end of the arm and spring-held as and for the purpose specified.

2. The combination with the arbor threaded at one end and suitably journaled in the frame, the cylinder suitably secured to the arbor, the longitudinal side rod, the sleeve fitting thereon and provided with radially-disposed notches, the recorder-arm secured to the sleeve, the feed-arm secured to the sleeve at one end, the nut secured to the opposite end of the feed-arm and meshing with the threaded end of the arbor, the spring on the recorder-arm provided with an end pin designed to engage one or other of the two notches in the sleeve as and for the purpose specified.

3. The combination with the arbor, suitably journaled, and the cylinder fitting thereon, of the recorder-arm pivotally held at one end and provided with an arc-shaped end, concentric to the pivoted end, the side bar of the frame, the bracket secured on the concentric end and the nut-screw extending through the bracket and resting on the side bar of the frame as and for the purpose specified.

4. The combination of the arbor, suitably journaled and the cylinder fitting thereon, of the recorder-arm pivotally held at one end and provided with an arc-shaped end concentric to the pivoted end, the side bar of the frame, the bracket secured on the concentric end and the nut-screw extending through the bracket and resting on the side bar of the frame and the handle pivoted on the end of the bracket and provided with a

notch designed to engage with the bar and locking the arm, as is to slide in the raised position as and for the purpose specified.

698,085. RADIATOR ATTACHMENT. JAMES R. WARD, St. Louis, Mo. Original application filed Oct. 14, 1900. Serial No. 79,688. Divided and this application filed Aug. 12, 1901. Serial No. 71,704. (No model.)

Claim.—1. A radiator attachment comprising a casing having a suitable inlet-opening, an inner tube depending from the top of the casing, an outlet-opening at the base of the inner tube, an outlet-pipe in communication with said outlet-opening, a cap or flange surrounding the tube and adapted to rest over the opening at the base of the casing, a tubular stem open at both ends carried by the flange and located within the tube and spaced therefrom, thereby affording communication by the passage thus formed, between the radiator and the outlet-pipe, substantially as set forth.

2. A radiator attachment comprising a casing having a suitable inlet-opening, a screw-cap covering the top of the casing, an inner tube depending from the center of the cap, an outlet-opening at the base of the casing located below the tube, an outlet-pipe in communication with said outlet-opening, a cap or flange surrounding the tube and adapted to rest over the opening at the base of the casing, a tubular stem open at both ends carried by the flange and located within the tube, and spaced therefrom, thereby affording communication by the passage thus formed, between the radiator and the outlet-pipe, substantially as set forth.

698,084. KNIVING-ENGINE. SALAMON E. WARD, Appleton, Wis. Filed May 1, 1901. Serial No. 80,005. (No model.)

Claim.—1. In a kniving-engine, a rot provided with a series of smaller ribs having continuous sliding recesses, of less depth than said ribs, a series of blades set in said recesses, each of said blades having its outer edge grooved or roughened, and a wood filling between each pair of adjacent blades.

2. A bar for kniving-engines, composed of two blades securely united in each other, one of said blades having a recess provided in its opposing side whereby to afford a filling-groove between the blades.

3. A bar for kniving-engines composed of two members securely united, one of said members being thicker than the other and having a recess provided in its opposing side.

4. A bar for kniving-engines, composed of two blades securely united to each other to form a compound bar and operated throughout their length and for a portion of their width by a groove having parallel side walls.

5. A bar for kniving-engines, composed of a number of members securely united to each other to form a compound bar, one or more of said members having a portion of its body removed whereby to provide cutting surfaces or blades and a filling-groove having parallel side walls between adjacent members.

6. A bar for kniving-engines, composed of a number of members, one or more of said members being recessed, whereby when the members are placed side by side to provide cutting surfaces or blades and a filling-groove between the blades.

7. A bar for kniving-engines, composed of a number of members securely united to each other to form a compound bar and operated throughout their length and for a portion of their width by a rectangular recess formed in one or more of said members.

8. A bar for kniving-engines having its outer sides grooved or roughened, as and for the purpose described.

698,085. SUSPENDER. ALFRED E. WARDER and EDWARD BALMER, Chicago, Ill. Filed Sept. 14, 1901. Serial No. 79,687. (No model.)

Claim.—1. The combination is a pair of suspenders, of the webbing as a crossing at the back, the adjustable ring through which the webbing passes at the place of crossing, the metallic loop-fasteners *c*, adapted to fit the trousers-bottom, the loops or openings of said fasteners being keyhole-shaped, the two arms of the loops being held from spreading by clips, and buttons *c* provided upon the clips of the front loops, to which buttons the rear loops are adapted to be buttoned, whereby the suspenders may be worn to support the trousers either at the front and back, or by buttoning the rear loops to the special buttons *c*, to support the trousers from the front loops only, said front loops being fastened at the sides of the trousers, substantially as and for the purpose specified.

2. A suspender comprising straps *a* as a crossing at the back, and having buttons at the end adapted to fit the trousers-bottom, and a special button *c* provided on the fasteners at the corresponding ends of both straps, the fasteners at the other ends being adapted to fasten either to the buttons of the trousers or to the special buttons *c* on the first-mentioned fasteners, whereby the suspenders may be worn to support the trousers either at the front and back or at the sides only, as set forth.

698,086. WRANCH. SAMUEL W. WARDWELL, Providence, R. I., and HENRY H. BAKER, Attleboro, Mass., assignors to Montague Wrench Co., Attleboro, Mass., a Corporation of Maine. Filed Aug. 20, 1901. Serial No. 79,689. (No model.)

Claim.—1. A wrench having a body comprising head portions, a handle, and jaw-guides intermediate said head and handle, all formed from one piece of sheet metal, and a movable jaw arranged between the head and handle on said guides, substantially as described.

2. A wrench having a body comprising head portions, a handle, and jaw-guides intermediate said head and handle, all formed from one piece of sheet metal, a movable jaw arranged between the head and handle on said guides, and a hardened jaw mounted between said head portions, substantially as described.

3. The combination is a wrench with a fixed jaw, a movable jaw, and a nut for moving the jaw, of a thread-bar to connect the movable jaw and the nut having a split end, a recess of substantially dovetail form in the edge of the movable jaw, and a wedge-shaped projection of the split end of the thread-bar extending into the recess and against which the split end of the thread-bar can be driven to effect its junction with the jaw, as described.

4. The combination is a wrench having a nut, and a jaw to be moved therefrom with a recess in its edge, of a wedge-shaped projection of the jaw extending into the recess, and a thread-bar to connect the nut and the jaw having a split end adapted to be forced upon said projection to effect a junction of the jaw and thread-bar, substantially as described.

5. The combination is a wrench, of a body comprising a handle por-

sides for the head and guides for a movable jaw intermediate the handle and the head, a hardened jaw inserted between the sides of the head and secured by rivets, and a removable jaw adjustable to and from the fixed jaw.

6. The combination is a wrench with a body formed from a single piece of sheet metal comprising a handle, sides for the head, and guides for a movable jaw intermediate the handle and the head, a hardened jaw inserted between the sides of the head and secured by rivets, a jaw movable in the guides and adjustable in position by a nut mounted in the handle, and a thread-bar engaging the nut and having a split end to enter a recess in the movable jaw to engage the split end of the thread-bar, substantially as described.

7. The combination is a wrench, with a fixed jaw, a movable jaw, and a nut for moving the jaw, of a substantially dovetail-shaped recess in the edge of the jaw, a wedge-shaped projection of the jaw extending into the recess, and a thread-bar having a split end, adapted to be entered into said recess and after having been so entered to be then thrust against said projection and opened to substantially fill the recess, for the purpose and in the manner substantially as described.

698,087. TELEPHONE-EXCHANGE SYSTEM. HARRY E. WIDMER, Chicago, Ill., assignor to the Stromberg-Carlson Telephone Manufacturing Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 28, 1901. Serial No. 48,714. (No model.)

Claim.—1. In a common-battery telephone-exchange system, the combination with a subscriber's line extending from the station to an exchange, the said station being provided with a telephone receiver and transmitter, of a common battery at the exchange connected with the said telephone-line and serving to supply the transmitter at the subscriber's station with current, a subsidiary circuit including the said common battery, means for creating in the said subsidiary circuit a signaling-current that is adapted to operate the diaphragm of the receiver at the subscriber's station to produce a calling-signal, and means for directing this current over the telephone-line, substantially as described.

2. In a common-battery telephone-exchange system, the combination with a subscriber's line extending from a station to an exchange, the said station being provided with a telephone receiver and transmitter, of a common battery at the exchange connected with the said telephone-line and serving to supply the transmitter at the subscriber's station with current, a local subsidiary circuit including the said common battery, means for creating in the said subsidiary circuit a signaling-current, a primary coil included in the subsidiary circuit, a secondary coil for the said primary, a trunk-line extending between a chief operator and the switching operator, a jack and plug for connecting the secondary coil with the said trunk-line at the chief-operator's desk, a jack at the switching-operator's desk also connected with the said trunk-line, and an operator's cord-circuit at the switching-operator's desk for connecting the said jack with the jack of the said subscriber, whereby the signaling-current created in the said subsidiary local circuit is passed over the trunk-line through the switching-operator's cord-circuit to the station to operate the diaphragm of the receiver at the said station if the receiver is off its hook, substantially as described.

3. In a common-battery telephone-exchange system, the combination with a subscriber's line extending from a station to an exchange, the said station being provided with a telephone receiver and transmitter, of a common battery at the exchange connected with the said telephone-line and serving to supply the transmitter at the subscriber's station with current, a local subsidiary circuit including the said common battery, means for creating a signaling-current in the said subsidiary circuit, a primary coil included in the subsidiary circuit, a secondary coil for the said primary, a trunk-line extending between a chief operator and the switching operator, a jack and plug for connecting the secondary coil with the said trunk-line at the chief-operator's desk, a jack at the switching-operator's desk also connected with the said trunk-line, and an operator's cord-circuit at the switching-operator's desk for connecting the said jack with the jack of the said subscriber, whereby the signaling-current created in the said subsidiary local circuit is passed over the trunk-line through the switching-operator's cord-circuit to the station to operate the diaphragm of the receiver at the said station if the receiver is off its hook, substantially as described.

698,088. POCKET GAME. JAMES E. WILSON, Baraboo, Wis. Filed Aug. 27, 1901. Serial No. 78,488. (No model.)

Claim.—1. A game comprising an inclined playing-field having goals at opposite points, and cylindrical playing-pieces each having one axis of movement only.

2. A game comprising an inclined playing-field with sides, a bottom and a transparent top, and having goals at opposite points therein, and cylindrical playing-pieces each having a single axis of rotation and a major diameter slightly greater than the distance between the said bottom and transparent top.

3. A game comprising a playing-field formed by a bottom, surrounding sides and a transparent top, and having goals at opposite points therein provided with pockets, and cylindrical playing-pieces having a single axis of rotation and the axis of each slightly less in length than the width of the said pockets.

4. A game having an inclined playing-field comprising a bottom, surrounding sides and a transparent top, and provided with goals at opposite points having pockets, and cylindrical playing-pieces having a single axis of rotation and each having its major diameter and length of axis slightly greater than the distance between the bottom and said top and the width of the pockets of the goals respectively.

5. A game consisting of an angular box comprising a bottom, surrounding sides and a transparent top, goals located in the angles of the box and having pockets therein with opposite parallel walls, and cylindrical playing-pieces, each of the playing-pieces having a single axis of rotation and the length of its axis slightly less than the distance between the walls of the pockets.

6. A game having a playing-field with goals, and cylindrical playing-pieces each having a single axis of rotation and adapted to enter said goals.

7. A game consisting of an inclined field comprising a bottom, surrounding sides and a transparent top, the playing-field being angular in contour and having goals arranged in the angles thereof, said goals being provided with pockets, and playing-pieces of cylindrical form each having a major diameter slightly greater than the distance between the bottom and top of the field and an axis slightly less in length than the width of the pockets.

8. A game comprising a playing-field having goals with pockets formed with outwardly and downwardly inclined bottoms, and cylindrical playing-pieces each having a single axis of rotation and the axis less in length than the width of the said pockets.

9. A game comprising a playing-field having goals, and cylindrical playing-pieces each having a single axis of rotation and adapted to enter the goals, the axis of the playing-pieces being less in length than the width of the goals.

698,089. STOP-MOTION FOR KNITTING-MACHINE. FRANK WILSON, Baraboo, Wis. Filed Dec. 2, 1900. Serial No. 36,372. (No model.)

Claim.—1. In combination in a stop-motion, a sweep, a feeder, means for entering the thread controlled by the operation of either the sweep or the feeder and connections controlled by the operation of the covering means for stopping the machine, substantially as described.

2. In combination, a stop-motion head having transmitting device, a standard supporting the head, controlling means supported on the stop-motion head to engage the thread and having a connection with the transmitting device extending substantially radially inward toward the standard, a sweep radially arranged at the top of the standard and a connection therefrom extending downwardly to operate the transmitting device through the said radial connection, substantially as described.

3. In combination, a stop-motion head having transmitting device, a standard carrying said head, a controlling device arranged on the head to engage the thread, an inwardly-extending substantially radial connection from said controlling device to the transmitting device, a sweep arranged above the stop-motion head at the top of the standard and an operating connection leading therefrom downwardly along the standard and thence radially outward, substantially as described.

4. In combination, the standard, a stop-motion head thereon having transmitting device, a sweep above the stop-motion head on the standard, a feeder supported substantially in the same horizontal plane with the stop-motion head, a detent arranged to be operated by the feeder, radial connections from the detent to the transmitting device of the stop-motion head, and a rod extending down from the sweep to operate the detent, substantially as described.

5. In combination, a standard, a stop-motion head supported thereon and having rotating arms, a feeder and a hook-catcher arranged adjacent to each other at the outer ends of said rotating arms, a plurality of sweeps arranged at a point above the stop-motion head and on the standard, said sweeps radiating from the standard, transmitting device carried by the stop-motion head and connections by which the sweeps and the feeders will operate said transmitting device, substantially as described.

6. In combination, a standard, a stop-motion head thereon having transmitting device, a plurality of feeders disposed at radial points about and supported on the stop-motion head, a plurality of sweeps supported at the upper end of the standard above the stop-motion head and radially arranged in respect to the standard, connections from said sweeps extending down to the transmitting device of the stop-motion head, said transmitting devices being also controlled by the feeders, and said feeders being in the path of the yarn from the bobbin to the overhead sweep, substantially as described.

7. In combination, a sweep, a stop-motion head supporting transmitting device, and a hook-catcher pivotally supported by the head and adjustable thereon about its pivot, substantially as described.

8. In combination, a stop-motion head having a plurality of arms, stop-motion connections, and a plurality of hook-catchers on being arranged at the outer end of each arm and adjustable independently of each other, substantially as described.

9. In combination in a stop-motion for knitting-machine, a sweep, a standard carrying said sweep radially at or near its upper end, a stop-motion head supported on the standard at some distance below the sweep, covering device for the yarn supported from said head, a hook-catcher also supported on said head, transmitting device carried by the head, and a connection between the covering means and said transmitting device extending radially in relation to the standard, substantially as described.

10. In combination in a stop-motion for knitting-machine, a standard, a sweep arranged at the upper end of the same, a stop-motion head arranged on the standard at a point some distance below the sweep, covering means for the yarn supported on the head, a feeder arranged radially in respect to the standard also supported on the head and transmitting device carried by the head and connections from both the overhead sweep and the radially-arranged feeder to the transmitting device whereby the latter are rendered operative by the movement of either the sweep or feeder, substantially as described.

11. In combination in a stop-motion for knitting-machine, a sweep, a feeder, transmitting device comprising a trip which includes covering means and connections whereby either the sweep or the feeder can independently operate said trip, substantially as described.

12. In combination in a stop-motion, transmitting device comprising main trip mechanism, having a tripping-spring, a supplemental trip controlling the same, and a feeder and sweep arranged to operate said supplemental trip, said feeder being located adjacent to and operating the supplemental trip directly while the sweep operates the same through intermediate connections, substantially as described.

13. In combination in a stop-motion for knitting-machine, a standard, power-transmitting connection, a tripping-spring connected thereto, a detent or trip for holding the spring against action, a sweep located at the upper end of the standard, and the vertically-movable rod with crank connections to the detent or trip, and said rod extending down from the overhead sweep, substantially as described.

14. In combination in a stop-motion, the power-transmitting device, a spring for operating them, connections leading from the spring comprising an arm 4, a slide-rod, a ball-crank between the arm 4 and slide-rod, a detent or trip for holding the arm 4, and detent means for controlling the detent, substantially as described.

15. In combination in a stop-motion, detent means, the arm 31, the ball-crank lever for operating the same, the radial rod for operating the ball-crank lever, a holding-ring 30, a spring connected with the ring and held under restraint thereby, a detent for holding the ring, said detent being arranged to be operated by the rotation of the arm, substantially as described.

16. In combination in a stop-motion, detent means, a stop-motion head, the arm within the head, trip connections to be operated thereby and means for operating the arm controlled by the detent, said means comprising the sliding rod and the ball-crank lever, said ball-crank lever being pivoted within the head, substantially as described.

17. In combination, the covering means, the tripping mechanism, to be operated by the covering means, the connection between them comprising a sliding rod for imparting the movement of the covering means to the tripping mechanism, and detent means controlling the covering means, substantially as described.

18. In combination, the covering means, the tripping mechanism, to be operated by the covering means, the connection between them comprising the slide-rod and the levers operated thereby and detent means controlling the covering means, substantially as described.

19. In combination, in a stop-motion, a plurality of detent means, a plurality of radially-sliding rods controlled thereby, ball-crank at the inner ends of said sliding rods, rotary arms having pins to be engaged by said levers, a main-spring 35, a ring to which said spring is connected, means for holding the ring arranged to be operated by the rotation of the arms and connections leading from the spring, substantially as described.

20. In combination in a stop-motion for knitting-machine, a fixed and a movable shear-blade, said fixed blade having a notch therein, a detent engaging said notch, and arranged to hold the movable blade, a spring connected with the movable blade, to operate it when released and a connection extending from the movable blade to operate the stopping device, substantially as described.

21. In combination in a stop-motion for knitting-machine, means for covering the thread, detent means arranged to control the operation of the covering means, and automatically-operating means to reset the covering means to normal position, substantially as described.

22. In combination in a stop-motion for knitting-machine, the device having the movable blade, with a spring for operating it, controlling means for the device, detent means controlling the same, power-transmitting device controlled through the operation of the detent means and connections therefrom to the device for resetting the same, substantially as described.

23. In combination, in a stop-motion, the device, a spring for operating it, substantially as described.

ing the same, detector means arranged to control the spring, connections operated by the spring when released including a trip mechanism, a spring released by said trip, connections operated by said spring leading to the stopping device and connections operated by said spring for resetting the same, substantially as described.

24. In combination, the same, a spring for operating the same, detector means controlling the spring, connections operated by the release of the spring and simultaneously with the closing of the shears and means operated in the final movement of said connections for resetting the same, substantially as described.

25. In combination, the same, a spring for operating the same, detector means for controlling the action of the spring, connections including a trip mechanism actuated by said spring, a mainspring released by said connections, a ring 36 operated by said spring and an arm 40 on said ring for returning the shears to their open condition, substantially as described.

26. In combination in a stop-motion for knitting-machine, a finger-finger, connections controlled by the said finger for stopping the machine and means for returning the finger to normal position consisting of the rock-shaft and operating means therefor, substantially as described.

27. In combination in a stop-motion for knitting-machine, a finger-finger, trip connections controlled thereby, a spring controlled by said trip connections and connections between the spring and the finger-finger for returning the same to normal position, substantially as described.

28. In combination in a stop-motion for knitting-machine, a finger-finger, trip connections controlled thereby, a spring controlled by said trip connections and connections between the spring and the finger-finger for returning the same to normal position, said connections including a ring 36 surrounding the trip mechanism and a connection between the same and the finger, substantially as described.

29. In combination, the standard, a stop-motion head thereon, a sweep above the stop-motion head on the standard, a finger supported substantially in the same horizontal plane with the stop-motion head, a detector arranged to be operated by the finger-finger directly, connections controlled by the detector, and connections extending from the sweep to the detector including the rod 7 extending along the standard and the radial connections from the lever and end of the rod to the detector, substantially as described.

30. In combination, the guide having the fingers and the finger having the end in the form of a closed loop through which one of the fingers projects, substantially as described.

31. In combination, the guide having one finger and a laterally open curved finger and the finger of loop form adapted to receive the curved finger through its opening substantially as described.

32. In combination, a guide having the two fingers projecting mouth or openings at angles to each other and a finger having an opening to receive one of the fingers, substantially as described.

33. In combination with the driving means, let-off connections, means on a moving part of the machine for operating the let-off connections and means carried by a moving part of the machine for resetting the let-off connections, substantially as described.

34. In combination, a let-off arm, a retaining device for the driving connection, operating means on a moving part of the machine, connections for operating the retaining device, normally out of the path of the said operating means, said connections being controlled by the let-off arm whereby when the let-off arm is operated the connection will be in line with the operating means, and means for resetting the connection, said means being carried by a moving part of the machine, substantially as described.

35. In combination, the let-off arm, the lever 36, a spring for pressing the lever upwardly, said lever being controlled by the let-off arm, the pin on a moving part of the machine for operating the lever, the retaining device for the driving connection, means connecting the lever with the retaining device, a cam on the moving part of the machine for forcing the lever down against the tension of the spring and out of line with the pin and means for resetting the connection when released from the pin, substantially as described.

36. In combination, the let-off arm, the vertically-movable rod controlled thereby, the lever connected with the rod to move vertically therewith and to have turning movement, the ring connected with the lever, a spring for forcing the lever upwardly, a retaining device for the driving connection, a pin on a moving part of the machine to engage the lever when raised, a cam for forcing the lever down out of contact with the pin and a spring for returning the ring and lever to normal position and thus resetting the retaining device when the lever is forced down by the cam.

37. In combination in a stop-motion, a plurality of sweeps, tripping mechanism controlled thereby and connections between the sweeps and the tripping mechanism comprising a plurality of rods 7, extending parallel and adjacent to the standard-springs 45 for applying tension to the rods and a collar 47 for adjusting the springs, said collar being supported

on the standard and being common to the several rods, substantially as described.

38. In combination, the covering means, a detent for holding the same ready to act, a feeler, and a sweep, said feeler and sweep being arranged to operate the detent, said connections for operating the stopping device, substantially as described.

39. In combination with a knitting-machine, a stop-motion comprising a support extending above the machine, the sweep arranged at the upper end of the said support, covering means arranged low down in relation to said sweep and at an intermediate point on said support, the thread being led first through the covering means then through the sweep and thence to the needles, the position of the covering means in relation to the sweep being such that the loose end of the thread must travel upwardly a considerable distance before pulling through the sweep, transmitting device and positively-operating connections between the covering means and said device, said connections being independent of the thread and actuated positively by the movement of the covering means, substantially as described.

40. In combination, the knitting-head, a standard extending upwardly and centrally in relation to said knitting-head, a stop-motion head on said standard, tripping mechanism forming part of said stop-motion head, covering means for the yarn, an arm reflecting from the stop-motion head to support the covering means, said covering means acting as the primary means for operating the tripping mechanism and connections leading from the tripping mechanism, substantially as described.

41. In combination with a knitting-head, a standard arranged above and centrally in relation to said knitting-head, a stop-motion head supported on the standard and having a centrally-arranged tripping mechanism, a supplemental tripping mechanism arranged on said head out beyond the central tripping mechanism and controlling the said central trip and a feeler said sweep controlling the said supplemental trip, substantially as described.

42. In combination with a knitting-head, a standard arranged centrally above the same, a stop-motion head supported thereon having transmitting connections arranged centrally, a trip mechanism arranged on the head out beyond the transmitting connections, a sweep, a connection extending radially of the head for controlling the tripping mechanism from the sweep, a feeler also controlling the tripping mechanism and a connection extending in a radial plane between the tripping mechanism and the centrally-arranged transmitting connections, substantially as described.

43. In combination, a plurality of covering means, one for each bobbin, detector means for controlling the covering means, and means connecting the covering means with the tripping device, substantially as described.

44. In combination, the central standard, the stop-motion head thereon, a tripping device, a sweep, connections between the sweep and the tripping device extending vertically and thence in a radial plane, a connection between the tripping device and stop-motion head extending in a radial plane and a vertical connection along the standard from the stop-motion head to the let-off connections, substantially as described.

45. In combination in a stop-motion, the main tripping mechanism having a spring, a supplemental tripping mechanism having a comparatively weak spring and including covering means, controlling means for the supplemental trip, connections between the supplemental trip and the main trip, said connections including means for increasing the power from the weaker to the stronger spring, substantially as described.

46. In combination in a stop-motion, the main tripping mechanism having a relatively stronger spring, a supplemental tripping mechanism having a comparatively weak spring, controlling means for the supplemental trip, connections between the supplemental trip and the main trip, said connections including means for increasing the leverage from the weaker to the stronger spring, and means whereby the stronger tripping-spring will reset the supplemental tripping mechanism and its weaker spring, substantially as described.

47. In combination in a stop-motion, the main tripping mechanism, a supplemental tripping mechanism arranged to operate the main trip, detector means controlling the supplemental trip, said main trip resetting upon the supplemental trip to reset the same, substantially as described.

48. In combination in a stop-motion, the covering means, the connections controlled by the operation of the covering means, with means whereby said connections when opened act to reset the covering means, substantially as described.

49. In combination in a stop-motion, tripping mechanism including covering means, main trip mechanism controlled by the operation of the covering means, said main tripping mechanism resetting upon the covering means to reset the same, substantially as described.

50. A knut-socket consisting of a plate having a series of spaced guides therein of different size, said plate being adjustable about its own axis, substantially as described.

51. In combination in a stop-motion for knitting-machine, a main and supplemental trip mechanism, detector means controlling the supplemental trip means whereby the main trip mechanism is controlled by the supplemental trip mechanism automatically, substantially as described.

52. In combination, the driving means, let-off connections, means for operating the let-off connections and means carried by a moving part of the machine for resetting the let-off connections, substantially as described.

53. In combination, the guide and feeler, one of said parts being of loop form and the other part having fingers at angles to each other, one of which projects into the loop, substantially as described.

54. In combination in a stop-motion tripping mechanism including detector means, detector means controlling the same and means for resetting the tripping mechanism automatically to be held by the said detent means, substantially as described.

55. In combination in a stop-motion, detector means controlled by the thread on its way to the feeding-point, tripping mechanism controlled by the detector means and means for resetting the tripping mechanism automatically, substantially as described.

698,090. STOP-MOTION FOR KNITTING-MACHINE. FRANK WILSON, Harrisburg, Pa. Filed Apr. 24, 1901. Serial No. 87,208. (No model.)

Claim.—1. In combination, the bobbin-stand adapted to be fixed to the machine comprising the standard and post extending up from the base of said stand, the stop-motion head supported by the standard, a sweep, the block for the sweep supported on the said standard and post, the lever and trigger below the base-plate, connections from the lever to the machine and means for operating the trigger from the stop-motion head, said means consisting of the rock-shaft extending down through the base-plate of the stand, substantially as described.

2. In combination, a bobbin-stand comprising a base-plate and a standard, said base-plate having means for supporting the bobbin, a stop-motion head supported on the standard, power-spring and trip mechanism carried by the base-plate and connections thereto from the stop-motion head, the said base-plate being adapted to be attached to the knitting-machine, substantially as described.

3. In combination, a lever, a spring for applying power thereon, a stop-motion head, a trigger attached to said lever, a rock-shaft with means for holding the lever, said trigger being arranged to be reset by the return movement of the lever after operating, and stop-motion connections leading to the trigger and arranged to be reset thereby, substantially as described.

4. In combination, a power-spring, a hand-lever connected therewith, a stop-motion head, a rotary stop-motion shaft extending from said head, a trigger attached to said rotary shaft to control the hand-lever, a part of said hand-lever being adapted to engage the trigger to reset the rotary shaft and to swing the trigger into locking connection with the hand-lever, substantially as described.

5. In combination, the stop-motion-controlling device, the trigger device, a hand-lever and power-spring comprised in the connection be-

tween them, a trigger for controlling the hand-lever and connected with the stop-motion-controlling device, said trigger and stop-motion-controlling device adapted to be reset by said hand-lever, substantially as described.

6. In combination in a stop-motion, controlling device, connections leading therefrom comprising a lever and a trigger, trigger device connected with the lever, said lever being arranged to give a positive resetting movement to the trigger, substantially as described.

7. In combination, stop-motion-controlling device, a lever, a power-spring and a trigger connected with the controlling device, said trigger having a tailpiece to be engaged by a part of the lever in resetting, substantially as described.

8. In combination, the stop-motion-controlling device, a connection leading therefrom including the trigger having the tailpiece, the member controlled by said trigger and arranged to reset the same by engaging the tailpiece and connections leading from said member to the trigger device, substantially as described.

9. In combination, a stop-motion head, a bobbin-stand having a standard supporting the same and having a base, a hand-operated member, a trigger carried by the said base, connections between the trigger and stop-motion head, said trigger and connections being arranged to be reset by the operation of the hand-operated member, substantially as described.

10. In combination, the trigger device, the rock-shaft for controlling the same, the finger on the rock-shaft to be operated when a knut or branch occurs at the needles, a spring for holding said rock-shaft in normal position, a stronger spring, connections between the same and the rock-shaft to turn the latter against the power of its spring and stop-motion device controlling the stronger spring, substantially as described.

11. In combination, the trigger device, stop-motion device for controlling the same arranged to be operated by the rotary movement of the machine, a spring for returning said device to normal position, a stronger spring with connecting means between the same and the said stop-motion device, and acting against the said weaker spring to operate the trigger device, and a second set of stop-motion device for controlling the said stronger spring, the said connecting means having a hinge-joint by which the first set of stop-motion device can be operated independently while the stronger spring is held inactive, substantially as described.

12. In combination, the trigger device, the rock-shaft controlling the same, the finger carried by the rock-shaft and arranged to be operated when a knut or branch occurs at the needles, the arm connected to the rock-shaft, a spring for returning the rock-shaft in normal position, a lever or arm, a stronger spring connected with said lever, a connection between the lever and the arm allowing the said arm to act independently of the lever, and stop-motion device controlling the lever, substantially as described.

13. In combination with a knitting-machine having a rotary head with a horizontal flange, a fixed base-ring flush with the upper surface of the flange and a brake device supported on the fixed ring and arranged to engage the upper surface of the said flange, substantially as described.

14. In combination, the rotary head having a horizontal flange, the fixed ring having its upper face flush with that of the flange and a brake device comprising a base secured to said fixed ring, a brake-chose arranged to engage a part of the rotary head and means carried by the base for operating the chose, substantially as described.

15. In combination, in a stop-motion for knitting-machine, a brake-chose, a rotary shaft, on counter-pin on the shaft to operate the chose, a base-plate in which the shaft is journaled, a spring within said base-plate controlling the shaft for operating the chose, and controlling means for the shaft, substantially as described.

16. In combination in a stop-motion for knitting-machine a brake-chose, a rotary shaft, on counter-pin to operate the chose, a base-plate in which the shaft is journaled, a spring within said base-plate for operating the chose, and controlling means for the chose, and means for adjusting the tension of the spring consisting of the ratchet base on the shaft to which the spring is attached and a detent for holding the ratchet, substantially as described.

17. In combination with the base-ring, the brake comprising a shaft, a base-plate in which the same is journaled secured to said base-ring, a latch-pin on the shaft, a catch-lever arranged to engage the latch-pin, said lever being pivoted to the base-plate and means for controlling the lever, all of said parts overlying the base-ring, substantially as described.

18. In combination, the brake-chose, the shaft carrying the same, the latch-pin on the shaft, the catch-lever for engaging the pin having a bracket end and connections for operating the lever, said connections including a base part which will permit the catch-lever to yield, substantially as described.

19. In combination, the knitting-head, the bobbin, comprising the catch for holding it inactive, trigger device, a rock-shaft with means operated thereby to control the trigger device, the spring for applying tension to said rock-shaft, stop-motion device connected to the rock-shaft

and a connection between the rock-shaft and the catch-lever, said catch-lever being held in operative position by the said spring, substantially as described.

20. In combination, the shipper connection, stop-motion, connections controlling the same, a spring for returning said stop-motion connections to normal position, a brake device including a catch to hold the brake inactive and a positive connection from the catch to the stop-motion device whereby said catch will be moved automatically to position to keep the brake off when the stop-motion device are returned to normal position, substantially as described.

21. In combination, the shipper connection, the rock-shaft with means operated thereby for controlling said connections, the spring, the arm *a* on the rock-shaft, the lever *m*, a power-spring connected therewith, a trigger for holding the said lever, a dotted link connection between the lever *m* and the arm *a*, the stop-motion finger connected with the arm *a*, the brake device, the catch therefor and the connection between the said catch and the arm *a*, substantially as described.

22. A thread-gage for stop-motions of knitting-machines consisting of an adjustable disk having different-sized holes therein and a guard-rod held at one end at the center of the disk extending thence adjacent to the opening thereof and having an elongated terminal extension, substantially as described.

23. In combination is a thread-gage, a disk having holes and adjustable axially and a guard-rod attached at one end at the center of the disk and extending thence adjacent to one of the holes, substantially as described.

24. In combination is a stop-motion, a power member, a trigger controlling the same, stop-motion connections thereto from the power member, said trigger device connected thereto from the power member, said power member being adapted to rest the trigger and the controlling device, substantially as described.

25. In combination is a stop-motion, controlling device, connections leading therefrom comprising a lever and a trigger, shipper device connected with the lever, said lever being arranged to give a positive resetting movement to the trigger, substantially as described.

698,091. STOP-MOTION FOR KNITTING-MACHINES. FRANK WILGERS, Harrisburg, Pa. Filed Apr. 24, 1901. Serial No. 57,369. (No model.)

Claim.—1. In combination is a stop-motion, the movable clear-blade, a lever operated thereby, trip mechanism released by the movement of the lever and means whereby the lever is reset upon by the trip mechanism to reset the clear-blade automatically by the movement of said lever, substantially as described.

2. In combination, the clear-blade trip mechanism, a supplemental trip mechanism, a connection between them whereby the supplemental trip mechanism will operate the main trip, said main trip resetting through the same connection to reset the supplemental trip, substantially as described.

3. In combination, the movable clear-blade, the tripping-spring therefor, a lever in direct engagement with part of said clear-blade, connections controlled by said lever and means whereby the lever is given a reverse movement to thereby reset the clear-blade, substantially as described.

4. In combination, the catch-lever, connections leading to the shipper device held by said catch-lever, a detent for holding the catch-lever, a swinging lever for operating the detent with means for operating the swinging lever and means for automatically resetting the swinging lever, substantially as described.

5. In combination, the connection leading to the shipper device, the arm *23* for controlling the same, the spring for applying a tension to said arm, the casing, the pivoted catch-lever within the casing engaging a part on the arm *23*, a detent within the casing engaging the said catch-lever with means for operating the detent consisting of a swinging lever pivoted within the casing and detector mechanism controlling the swinging lever, substantially as described.

6. In combination is a stop-motion, connections leading to the shipper device, a catch-lever for holding said connections, a casing in which the catch-lever is pivoted, a swinging lever having an arm thereof projecting outside the casing and means for operating the said arm, and a detent for the catch-lever, said swinging lever being arranged to operate the detent, the said catch-lever, swinging lever and detent being pivoted within the casing, substantially as described.

7. In combination, the stop-motion head, tripping mechanism carried by the head including a swinging lever, a supplemental trip for operating the main trip and resetting means for the supplemental trip comprising a lever arranged within the head, substantially as described.

8. In combination, the stop-motion head, tripping mechanism carried by the head, a supplemental trip for operating the main trip and resetting means for the supplemental trip comprising the pivoted lever *30* arranged within the head, substantially as described.

9. In combination is a stop-motion, tripping mechanism comprising a catch-lever *10* having a shoulder, means controlled thereby including the pin *21* carried by said means and held by said shoulder, a detent for said catch-lever, means controlling the detent, said catch-lever having a part to be engaged by the pin to be reset thereby, substantially as described.

10. In combination is a stop-motion head, the connection leading to the shipper device, the catch-lever controlling said connections, a detent for holding the catch-lever, a swinging lever for operating the detent and a resetting-lever operated by the said connections for resetting the swinging lever, substantially as described.

11. In combination is a tripping mechanism for stop-motions, a detent, a lever controlled thereby, a member controlling the connections leading to the shipper device and a shoulder on the lever arranged at an inclination to a radial line from the pivot of the lever along which line the said member is adapted to move approximately, substantially as described.

12. In combination is a tripping mechanism for stop-motions, a detent, a lever having a long arm bearing thereon and having an arm with a shoulder thereon comparatively close to its pivot, a member to engage said shoulder and arranged to move along a line substantially radial away from said pivot when released from the shoulder, connections leading to the shipper device controlled by said member, the said shoulder being arranged at an inclination to the radial line from said pivot, substantially as described.

13. In combination, is a tripping mechanism for stop-motions, a swinging lever *14*, connections controlled thereby and a resetting device for said lever moving along a path inclined to the longitudinal axis of the lever, substantially as described.

14. In combination, the swinging lever *14* of the trip mechanism, connections controlled thereby and a lever *30* pivoted to one side of the swinging lever and having a part to reset the lever, said part moving in a direction longitudinally of the lever, substantially as described.

15. In combination is a tripping mechanism for stop-motions, a swinging lever *14*, connections controlled thereby, said lever having a cam-surface thereon and a resetting-roller movable in a direction longitudinally of the lever to contact with said cam-surface, substantially as described.

16. In combination is a stop-motion, the rotary bobbin-stand, a stop-motion head carried thereby, a series of pins carried by the stand and revolving therewith, means for controlling the position of the series of pins, said means being in turn controlled by the stop-motion head and connections to the shipper device operated by the pins, substantially as described.

17. In combination with a knitting-head, shipper connection, a rotary bobbin-stand, stop-motion-controlling device carried by the said

stand, a standard supporting the stop-motion-controlling device above the knitting-head and arranged axially in relation to said head and a connection from the stop-motion-controlling device to the shipper connection comprising a rod arranged axially of and extending along the standard, the stop-motion-controlling device also being arranged axially in relation to the standard, substantially as described.

18. In combination, the rotary bobbin-stand, stop-motion-controlling device carried thereby, shipper connections and transmitting connections between the controlling device and the shipper connections comprising the vertically-movable stem arranged axially in support to the rotary bobbin-stand, substantially as described.

19. In combination, the rotary bobbin-stand, stop-motion-controlling device carried thereby, shipper connections, a centrally-arranged tripper-foot vertically movable, and means for holding the foot normally up against the stop-motion-controlling device, said tripper-foot when in its lower position serving to operate the shipper connections, substantially as described.

20. In combination, the rotary bobbin-stand, a standard extending up therefrom, the stop-motion-controlling device, the shipper connections, the centrally-arranged tripper-foot having the pins guided in the bobbin-stand and having a hollow stem extending up around the standard, and means for normally holding said stem up operated by said controlling device, substantially as described.

21. In combination, the stop-motion head, a standard supporting the same, a lever *23* pivoted beneath the stop-motion head under spring tension and controlled by the stop-motion device, the vertically-movable connection extending along the supporting-standard of the stop-motion head, the catch for holding the same up controlled by the said lever *23*, and means leading to the shipper device controlled by the falling of the said connection, substantially as described.

22. In combination, the shipper connection, a rotary bobbin-stand comprising a standard, stop-motion-controlling device supported by the standard and a hollow stem surrounding the standard, said stem being vertically movable controlled by the stop-motion device at its upper end and controlling the shipper connection at its lower end, substantially as described.

23. In combination with a rotary knitting-head, a rotary bobbin-stand supported independently of the rotary parts of said head and above the same, means for retaining said stand and stop-motion device carried by the stand, substantially as described.

24. In combination with a rotary knitting-head, a rotary bobbin-stand and a rotary stop-motion mechanism supported independently of and axially above the said head and means for resetting said stand and stop-motion mechanism, substantially as described.

25. In combination with a rotary knitting-head, a rotary bobbin-stand and a rotary stop-motion mechanism, means for supporting the stand and stop-motion mechanism independently of the head and above the same and means for driving the bobbin-stand and stop-motion mechanism from the rotary head, substantially as described.

26. In combination with a rotary knitting-head, a rotary bobbin-stand, stop-motion mechanism, means for supporting the stand and stop-motion mechanism independently of the head and a loose connection for driving the stand and stop-motion mechanism from the head, substantially as described.

27. In combination, with a rotary knitting-head, a rotary bobbin-stand above the head, stop-motion mechanism, means for supporting the stand and stop-motion mechanism independently of the knitting-head, said supporting means having an opening through which the thread passes from the bobbin to the knitting-head, substantially as described.

28. In combination with the rotary head of a knitting-machine, a rotating stop-motion, means for supporting the same independently of the head, means for rotating the stop-motion and shipper connections operated by said stop-motion, substantially as described.

29. In combination, the rotary knitting-head, a rotary bobbin-stand and stop-motion mechanism above the same and a loose connection between the spindle of the knitting-head and the stand and stop-motion mechanism, substantially as described.

30. In combination, the rotary knitting-head, a ring-shaped support arranged concentric with the axis of the knitting-head and a bobbin-stand with stop-motion mechanism arranged to rotate on said ring-shaped support, substantially as described.

31. In combination, the rotary knitting-head, a support above the said head and a bobbin-stand having a ring rotative on the said support to rotate, means for driving the bobbin-stand and stop-motion mechanism carried by the bobbin-stand, substantially as described.

32. In combination, the bobbin-stand supported to rotate, rotary stop-motion mechanism carried by the stand, the rotary knitting-head, and the pin-and-fork connection between the spindle of the knitting-head and the bobbin-stand, substantially as described.

33. In combination is a stop-motion, a sweep having an open-

mouthed bent portion, to rest on the pivot-pin and having a tailpiece and a rod engaging the tailpiece, substantially as described.

34. In combination is a stop-motion, a sweep having an upwardly-bent portion leaving a downwardly-directed opening to receive the pivot, and a dotted blank in which the sweep is pivoted, said blank having a guard above the bent part of the sweep, substantially as described.

35. In combination, the sweep, the standard, the rods extending down alongside the standard, the transmitting connections controlled by said rods and springs for applying a tension to the rods and means for adjusting the tension of said springs independently, said means being carried by the standard, substantially as described.

36. In combination, a stop-motion head, a standard extending up therefrom, a sweep at the upper part of said standard, a finger-dog supported on the head, tripping mechanism supported by the head, a detent for controlling the tripping mechanism and a sweep-rod extending down from the sweep, said sweep-rod and finger-dog being arranged to operate the detent directly and in the same direction, substantially as described.

37. In combination, the rotary stop-motion head, the finger pivoted to fall opposite to the direction of rotation and a stop for holding the finger against the influence of centrifugal force, substantially as described.

38. In combination, the rotary stop-motion head, the finger pivoted to fall opposite to the direction of rotation and a stop for holding the finger against the influence of centrifugal force, the guide, said stop being on the guide, substantially as described.

39. In combination is a stop-motion, a knot-catcher comprising the two plates arranged one over the other with a space between them and having slots diverging from the thread-gage whereby the mouth of said slots are located at different points along the edge of the said plates, the said thread-gage being formed at the junction of the slots, substantially as described.

40. In combination, the rotary bobbin-stand, stop-motion-controlling device carried thereby, shipper connections, the vertically-movable connections leading from the controlling device and the tripper-foot carried by the bobbin-stand, said tripper-foot being arranged concentric with the axis of rotation and having a plurality of pins disposed at different points about said axis, substantially as described.

41. In combination is a stop-motion, a main trip mechanism, means for controlling the same, a casing including the said main trip mechanism and a resetting device within said casing, substantially as described.

42. In combination is a stop-motion, a casing, a catch-lever, a detent for holding said catch-lever, connections controlled by the catch-lever, a swinging lever and a resetting-lever, the said catch-lever, detent, swinging lever and resetting-lever all being pivoted within the casing, substantially as described.

43. In combination with a rotary knitting-head, stop-motion mechanism arranged above the head, supporting means for said stop motion mechanism independent of the knitting-head, and means for driving the stop-motion mechanism from the head, substantially as described.

44. In combination with a knitting-head, a ring-shaped support above the same, a stop-motion mechanism supported on said ring-shaped support and a loose connection from the knitting-head to the stop-motion mechanism, substantially as described.

45. In combination with a rotary knitting-head, stop-motion mechanism arranged to rotate and supported independently of and axially above the said head and means for rotating the said mechanism, substantially as described.

46. In combination with a rotary knitting-head, a stop-motion, means for supporting the stop-motion independently of the knitting-head, carrying a ring-shaped support above the said head and means for rotating the stop-motion, substantially as described.

47. In combination with a rotary knitting-head, stop-motion mechanism above the head including rotary parts, means for supporting the said rotary parts independently of the head and a loose connection for driving the rotary stop-motion parts from the head, substantially as described.

48. In combination, a rotary knitting-head, stop-motion-controlling device above the same, a rotary support for said device, means for rotating the same independently of the rotary knitting-head, shipper connections and a connection leading thence from the stop-motion-controlling device arranged axially above the knitting-head, substantially as described.

49. In combination, a rotary bobbin-stand, rotary stop-motion means carried thereby, a loose connection from said rotary bobbin-stand to the knitting-head, and means for supporting the rotary bobbin-stand independently of the knitting-head, substantially as described.

50. In combination, the stop-motion head, an axial standard for supporting the same above the knitting-head and a connection leading from the stop-motion head consisting of the rod extending along the standard, both the standard and the rod being arranged axially in relation to the knitting-head, substantially as described.

61. In combination, stop-motion-controlling device, a standard extending axially above the leading-head and supporting the said stop-motion device and a connection leading from the stop-motion head and comprising a vertically-movable rod arranged axially of the leading-head and extending longitudinally of the standard, substantially as described.

62. In combination, stop-motion-controlling device, a rotary hobble-stand, a standard, stop-motion-controlling device at the upper end of the standard, and a vertically-movable rod controlled at its upper end by said device and having a series of pins at its lower end to operate the stop-motion connections, said pins being disposed at points at equal radial distances from the standard and to drop into the plane of the stop-motion connections, substantially as described.

63. In combination is a rotary stop-motion, a pivoted finger and a guide having a stop to hold said finger against the action of centrifugal force, substantially as described.

698,092. SAFETY WATCH-POCKET. ROBERT C. WELCH, Montreal, Canada. Filed May 29, 1901. Serial No. 68,448. (No model.)

Claim.—A safety watch-pocket closed at its top and bottom and partly closed on both side edges thereof, said pocket provided on its inner edge with a small opening adapted for the passage of a watch chain or guard, and also provided at its outer side edge with a larger opening arranged to permit of the ready introduction or withdrawal, by hand, of a watch into or from the pocket, substantially as and for the purposes set forth.

698,098. HYDRAULIC OR SIMILAR POWER APPARATUS. CHARLES C. WORTHINGTON, Danforth, E. J. Filed Aug. 20, 1906. Serial No. 57,792. (No model.)

Claim.—1. The combination with a hydraulic or similar cylinder and apparatus for forcing fluid into the cylinder, of a piston subjected on opposite sides to the pressure of the fluid in the cylinder and in the apparatus during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of the fluid in the apparatus during the exhaust of fluid from said cylinder, mechanism controlled by the movement of said piston for controlling the supply of power to said apparatus, and adjustable means for sliding the pressure on one side of the piston, substantially as described.

2. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a pump for forcing fluid into the cylinder, of a piston subjected on opposite sides to the pressure of the fluid on the cylinder and pump sides of the valve during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of fluid on the pump side during the exhaust of fluid from said cylinder, and mechanism controlled by the movement of said piston for controlling the supply of power to said pump, substantially as described.

3. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a pump for forcing fluid into the cylinder, of a piston subjected on opposite sides to the pressure of the fluid on the cylinder and pump sides of the valve during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of fluid on the pump side during the exhaust of fluid from said cylinder, mechanism controlled by the movement of said piston for controlling the supply of power to said pump, and adjustable means for sliding the pressure on one side of the piston, substantially as described.

4. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a steam-pump for forcing fluid into the cylinder, of a piston subjected on opposite sides to the pressure of the fluid on the cylinder and pump sides of the valve during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of fluid on the pump side during the exhaust of fluid from said cylinder, and a valve actuated by the movement of said piston for controlling the supply of steam to said pump, substantially as described.

5. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a steam-pump for forcing fluid into the cylinder, of a piston subjected on opposite sides to the pressure of the fluid on the cylinder and pump sides of the valve during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of fluid on the pump side during the exhaust of fluid from said cylinder, a valve actuated by the movement of said piston for controlling the supply of steam to said pump, and adjustable means for sliding the pressure on one side of the piston, substantially as described.

6. The combination with a hydraulic or similar cylinder and apparatus for forcing fluid into the cylinder, of a piston subjected on opposite sides to the pressure of the fluid in the cylinder and in the apparatus during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of the fluid in the apparatus during the exhaust of fluid from said cylinder, and mechanism controlled by the movement of said piston for controlling the supply of power to said apparatus, substantially as described.

7. The combination with a hydraulic or similar cylinder and apparatus for forcing fluid into the cylinder, of a differential piston subjected on opposite sides to the pressure of the fluid in the cylinder and in the apparatus during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of the fluid in the apparatus during the exhaust of fluid from said cylinder, and mechanism controlled by the movement of said piston for controlling the supply of power to said apparatus, substantially as described.

8. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a steam-pump for forcing fluid into the cylinder, of a steam-accumulator between the pump and cylinder controlling the supply of steam to the pump by its piston, a piston subjected on opposite sides to the pressure of the fluid on the cylinder and pump sides of the valve during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of fluid on the pump side during the exhaust of fluid from said cylinder, and a valve actuated by the movement of said piston for controlling the supply of steam to said accumulator, substantially as described.

9. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a steam-pump for forcing fluid into the cylinder, of a steam-accumulator between the pump and cylinder controlling the supply of steam to the pump by its piston, a differential piston subjected on opposite sides to the pressure of the fluid on the cylinder and pump sides of the valve during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of fluid on the pump side during the exhaust of fluid from said cylinder, and a valve actuated by the movement of said piston for controlling the supply of steam to said accumulator, substantially as described.

10. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a steam-pump for forcing fluid into the cylinder, of a steam-accumulator between the pump and cylinder controlling the supply of steam to the pump by its piston, a piston subjected on opposite sides to the pressure of the fluid on the cylinder side of the valve and in the accumulator during the admission of fluid to the hydraulic cylinder and on both sides to

the pressure of fluid in the accumulator during the exhaust of fluid from said cylinder, and a valve actuated by the movement of said piston for controlling the supply of steam to said accumulator, substantially as described.

11. The combination with a hydraulic or similar cylinder and its valve for controlling the supply and exhaust of fluid for said cylinder, and a steam-pump for forcing fluid into the cylinder, of a steam-accumulator between the pump and cylinder controlling the supply of steam to the pump by its piston, a differential piston subjected on opposite sides to the pressure of the fluid on the cylinder side of the valve and in the accumulator during the admission of fluid to the hydraulic cylinder and on both sides to the pressure of fluid in the accumulator during the exhaust of fluid from said cylinder, and a valve actuated by the movement of said piston for controlling the supply of steam to said accumulator, substantially as described.

12. The combination with a hydraulic or similar cylinder and its valve mechanism, of cylinder 20 and piston 4, pipes 21, 22 connecting said cylinder 20 on opposite sides of the piston with the fluid-spaces on opposite sides of the valve mechanism during the admission of fluid to said cylinder and with the supply side of the valve mechanism by both pipes during the exhaust of fluid from the cylinder, a power apparatus controlled by the movement of said piston, and adjustable valve 6 on said pipe 22, substantially as described.

13. The combination with a hydraulic or similar cylinder and its valve mechanism, of cylinder 20 and piston 4, pipes 21, 22 connecting said cylinder on opposite sides of the piston with the fluid-spaces on opposite sides of the valve mechanism during the admission of fluid to said cylinder and with the supply side of the valve mechanism by both pipes during the exhaust of fluid from the cylinder, a power apparatus controlled by the movement of said piston, and a spring or equivalent device tending to move the piston in one direction, substantially as described.

14. The combination with a hydraulic or similar cylinder and its valve mechanism, of cylinder 20 and piston 4, pipes 21, 22 connecting said cylinder on opposite sides of the piston with the fluid-spaces on opposite sides of the valve mechanism, a power apparatus controlled by the movement of said piston, and means for applying a constant adjustable pressure to said piston tending to move it in one direction, substantially as described.

15. The combination with a hydraulic or similar cylinder and its valve mechanism, of cylinder 20 and piston 4, pipes 21, 22 connecting said cylinder on opposite sides of the piston with the fluid-spaces on opposite sides of the valve mechanism, a power apparatus controlled by the movement of said piston, a spring or equivalent device tending to move the piston in one direction, and lever 17 between piston 4 and the power apparatus provided with one or more arms 28 for applying adjustable pressure tending to move the piston in one direction, substantially as described.

16. The combination with a hydraulic or similar cylinder and its valve mechanism, of cylinder 20 and piston 4, pipes 21, 22 connecting said cylinder on opposite sides of the piston with the fluid-spaces on opposite sides of the valve mechanism during the admission of fluid to said cylinder and with the supply side of the valve mechanism by both pipes during the exhaust of fluid from the cylinder, pump 1, valve 6 controlling the supply of steam to said pump, and connection between piston 4 and valve 6 for controlling the valve by the piston, substantially as described.

17. The combination with a hydraulic or similar cylinder and its valve mechanism, of cylinder 20 and piston 4, pump 1, steam-accumulator 11, means for controlling the passage of steam to the pump by the position of the accumulator-piston, valve 6 controlling the supply of steam to the accumulator and pump, pipes 21, 22 connecting cylinder 20 on opposite sides of the piston with the hydraulic cylinder and accumulator during the admission of fluid to said cylinder and with the accumulator by both pipes during the exhaust of fluid from the cylinder, and connection between piston 4 and valve 6 for controlling the valve by the piston, substantially as described.

18. The combination with a hydraulic or similar cylinder, of cylinder 20 and piston 4, pipes 21, 22 connecting said cylinder on opposite sides of the piston with the fluid-spaces on opposite sides of the valve mechanism, pump 1, steam-accumulator 11, means for controlling the passage of steam to the pump by the position of the accumulator-piston, valve 6 controlling the supply of steam to the accumulator and pump, pipes 22 connecting cylinder 20 on one side of the piston with the accumulator, pipe 21 connecting with cylinder 20 on the opposite side of the piston, and a valve-chamber and valve for the hydraulic cylinder arranged to connect pipe 21 with the hydraulic cylinder on the admission of fluid and when the cylinder-valve is closed and to connect pipe 21 with the accumulator on the exhaust, and connection between piston 4 and valve 6 for controlling the valve 6 by the piston, substantially as described.

698,094. BELT-DRIVE REVERSER. THOMAS WILKINSON, West-
minster, and JOHN HARRIS, Croydon, Surrey, England. Filed Dec.
9, 1901. Serial No. 58,821. (No model.)

Claim.—1. The combination of the pair of cylinders a, c the pair of cylinders b, d the pistons e fitting these cylinders the rods f coupling the pistons in each pair of cylinders, means for admitting air or fluid under pressure continuously to the space between the pistons in each pair, a valve-chamber, two small cylinders at opposite ends of this chamber, pistons fitting these small cylinders, a rod coupling the pistons together, valve mechanism operated by the movement of the pistons in these small cylinders by which air or fluid is alternately admitted to the rear end of the cylinder a and to escape from rear end of b or to enter the rear end of b and escape from a, a pipe passing from the rear end of one of the small cylinders to some point at the side of the small cylinder c and another similar pipe passing from the rear end of the other small cylinder to the side of the small cylinder d.

2. The combination of the pair of cylinders a, c the pair of cylinders b, d, the pistons e fitting these cylinders the rods f coupling the pistons in each pair of cylinders, means for admitting air or fluid under pressure continuously to the space between the pistons in each pair whereby owing to the difference in area between the pistons the pistons are normally driven back into their cylinders, means for admitting air or fluid under pressure to the rear end of the larger cylinder of one pair to drive forward the pistons of that pair while at the same time air or fluid is allowed to escape from the rear end of the larger cylinder of the other pair and the pistons of this pair allowed to make their backward stroke.

3. The combination of two parallel pairs of cylinders each pair consisting of a cylinder closed at its rear end and a smaller cylinder projecting from its front end and opening into it, the pistons of these cylinders, rods connecting the pistons of each pair, means for admitting fluid under pressure continuously to the space between the pistons of each pair, a port in the side of each small cylinder past which the piston of that cylinder travels to and fro alternately opening that port to the outer air and to fluid under pressure in the space between the pistons, pipes leading from these ports to two small cylinders, the pistons of these cylinders simultaneously moved to and fro at the time when one of the above ports is opened to the air and the other to fluid under pressure, and valve mechanism operated by the to-and-fro movement of these pistons to alternately admit fluid under pressure to the rear end of the larger cylinder of one pair and then to the other and simultaneously allow it to escape from the rear end of the larger cylinder which is not having fluid under pressure applied to it.

4. The combination of two parallel pairs of cylinders each pair consisting of a cylinder closed at its rear end and a smaller cylinder projecting from its front end and opening into it, the pistons of these cylinders, rods connecting the pistons of each pair, means for admitting fluid under pressure continuously to the space between the pistons of each pair, and means for alternately admitting fluid under pressure to the rear end of the larger cylinder of one pair of cylinders and then to the other and simultaneously allowing it to escape from the rear end of the larger cylinder which is not having fluid under pressure applied to it.

5. The combination of two parallel pairs of cylinders each pair consisting of a cylinder closed at its rear end and a smaller cylinder projecting from its front end and opening into it, the pistons of these cylinders, rods connecting the pistons of each pair, means for admitting fluid under pressure continuously to the space between the pistons of each pair, two swinging plate-arms, rods connecting these arms to the two pairs of pistons and means for alternately admitting fluid under pressure to the rear end of the larger cylinder of one pair of cylinders and then to the other and simultaneously allowing it to escape from the rear end of the larger cylinder which is not having fluid under pressure applied to it.

698,095. SKID. BENJAMIN H. ALPHE, Louisville, Ky., assignor
to the Alvey-Pergason Co., Louisville, Ky., a Corporation of Kentucky.
Filed Mar. 12, 1901. Serial No. 58,840. (No model.)

Claim.—1. In a skid the combination with the track having two pairs of lateral wheels, of the side plates or skids adapted to be upwardly inclined to a wagon or other point of delivery and formed with lateral channels in which said wheels are held from any movement lateral to the track, the said channels having a head at the upper end whereby the upper pair of wheels is positively deflected below the normal path of travel and relative to the rear pair to bring the track to a delivery position, substantially as set forth.

2. In a skid the combination with the track having two pairs of la-

oval wheels, of the side plates or ribs A adapted to be upwardly inclined to a wagon or other point of delivery and having the wheel-supporting surfaces 2 and the overhanging walls 3 at an angle to the surface 2.

3. In a side the combination with the truck having two pairs of lateral wheels, of two U-beams constituting sides A arranged with their channels opposite each other to receive said wheels, said beams being bent to form overhanging walls 3 at an angle to the supporting-surfaces 2.

4. In a side the combination with the supporting or inclined portion, of a truck fitted to travel thereon and brake-chains carried by the truck and bearing laterally against said inclined portion, said chains having their engaging portions nearly in line with but a little back of their pivots so as to substantially act upon the retrograde movement of the truck.

5. In a side the combination with the supporting or inclined portion, of a truck fitted to travel thereon, brake-chains pivoted on the truck and bearing laterally against said inclined portion, a spring for holding said chains in contact with said inclined portion, and means for releasing said chains.

698,096. CIRCUIT-BREAKER. HENRY P. BALL, New York, N. Y., assignor to General Insulator and Light Company, of New York, a Corporation. Filed May 21, 1901. Serial No. 61,516. (No model.)

Claim.—1. In an automatic circuit-breaker, the combination of a switchboard, a hand-lever on the front of the switchboard, a bracket on the back of the switchboard, an oil-can, circuit-terminals in the oil-can, an oscillating lever, a bridge-piece carried by the lever and adapted to coast with the circuit-terminals, a resilient device for normally holding the circuit open between the bridge-piece and the circuit-terminals, a link interposed between the hand-lever and the oscillating lever and provided with a slot near its rear end, a pin located in said slot and pivotally connecting said oscillating lever to said link, an electromagnet, a latch device adapted to coast with said oscillating lever, and a device carried by the link which, when the hand-lever is depressed, will act to release the latch from its engagement with the oscillating lever and permit the circuit-breaker to open.

2. In an automatic circuit-breaker, the combination of a hand-lever, an oscillating lever carrying a bridge-piece, a spring device adapted to exert tension upon the oscillating lever, a link between said hand-lever and said oscillating lever provided with an elongated slot at its rear end, a pin located in said slot and pivotally connecting said oscillating lever with said link, an electromagnet, a latch device which coacts with said oscillating lever, and a device carried by the link which, when the hand-lever is depressed, will actuate the latch to release the oscillating lever.

3. In an automatic circuit-breaker, the combination of a bracket on the rear of a switchboard, an oil-can carried by said bracket, partitions in said oil-can, circuit-terminals carrying spring-contacts located in said oil-can, an oscillating lever, a bridge-piece carried by said lever, and an insulating-disk carried by said lever, which coacts with said partitions in said oil-can.

698,096.

698,097. ELECTRICAL INSULATOR. HENRY P. BALL, New York, N. Y., assignor to General Insulator and Light Company, of New York, a Corporation. Filed Aug. 31, 1901. Serial No. 73,980. (No model.)

Claim.—1. An insulator, comprising a body portion having the shape of a long cylinder with parallel grooves in its surface, and a supporting-flange of greater diameter.

2. An insulator comprising a body portion having the shape of a long corrugated cylinder, and a supporting-flange of greater diameter.

3. The combination with an insulator, consisting of a corrugated body portion and a supporting-flange, of means for securing said insulator upon a switchboard, floor, slab, or other similar body.

4. The combination with an insulator, consisting of a corrugated body portion and a supporting-flange, a support for said insulator, a rod traversing said insulator, and a clamping device on the end of said rod.

698,098. CARPET-SWEEPER. JONATHAN BARNES, RICHARD W. KINTON, and WILLIAM H. KINTON, Asbury, England. Filed Dec. 23, 1901. Serial No. 57,808. (No model.)

Claim.—1. In a carpet-sweeper, a socket to receive the handle, constructed with an aperture at one side, a clamping-plate fitted into the aperture, and a screw to clamp the plate in position and clamp the end of the handle, substantially as described.

2. The combination with a carpet-sweeper of a socket A to receive the handle B, provided with an aperture O at one side of a clamping-plate

D, a screwing-rod on one edge of the clamping-plate, and a screw E at the other edge passing through a lug in the said plate and into a hole in the socket, substantially as described.

698,099. ELECTRICAL RAILROAD TRACTION APPARATUS. ANDREW A. BURNER, Chicago, Ill. Filed July 12, 1901. Serial No. 61,518. (No model.)

Claim.—1. The combination in electric railroad traction apparatus of a laterally-movable non-conducting protector d or covering formed of a block or strip of wood or other suitable non-conducting material with an electric conductor f lying close to the surface of the railroad rail substantially as described.

2. The combination in electric railroad traction apparatus of an electrical collector b together with a laterally-movable non-conducting protector d or covering formed of a block or strip of wood or other suitable non-conducting material with an electric conductor f lying close to the surface of the railroad rail substantially as described.

3. The combination in electric railroad traction apparatus of a protective covering for the working conductor consisting of a series of short lengths of wood or other non-conducting material having their ends interlocked and adapted for lateral movement in combination with a conductor arranged near the surface of the railroad-bed.

698,100. SPIKE-MACHINE. HERMAN H. BRIDGER, Pittsburg, Pa., assignor to two-thirds to John Wolterbecker, Pittsburg, Pa. Filed Oct. 2, 1900. Renewed Sept. 27, 1901. Serial No. 76,780. (No model.)

Claim.—1. In a spike-machine, a bed-plate having its top provided with recesses formed therein having integral side walls and intermediate vertical walls combined with spike-forming mechanism upon said plate between the walls therein and so arranged that the strain upon the die in forming the spike will fall upon the side walls, and means for simultaneously moving a blank laterally and longitudinally.

2. In a spike-machine, a bed-plate, a stationary and laterally-movable die thereon, a reciprocating point-forming mechanism, a header-block provided with a forming-die arranged to bend the head of the spike laterally, and means for moving the blank simultaneously laterally and longitudinally.

3. In a spike-machine, a bed-plate, a stationary and a movable die thereon, a header, point-forming mechanism, and means for moving a blank simultaneously laterally and longitudinally within the dies after it has been covered from a bar of material.

4. In a spike-machine, a bed-plate, a stationary and a movable die thereon, a header, point-forming mechanism, means for moving a blank simultaneously laterally and longitudinally, and means for adjusting each of the said parts independently of the other.

5. In a spike-machine, a bed-plate, means thereon for covering a

blank from a bar of material, a movable stop for determining the length of the blank, and means for moving the blank simultaneously laterally and longitudinally within the dies as the stop is moved to the rear.

6. In a spike-machine, a bed-plate provided with side and end walls, the end wall being recessed, a perforated cutting-blade secured to the end wall, a reciprocating blade arranged to move longitudinally against the stationary blade, a reciprocating rod at the side of the machine, and a spring mounted on said rod for returning it and the reciprocating blade to their normal positions.

7. In a spike-machine, a bed-plate provided with side and end walls, the end wall being recessed, cutting mechanism adjacent to said recess, a stationary die bearing against one of the side walls, a die-holder bearing against the other wall, a die in said holder, a block mounted in said wall and provided with a roller and a wedge-shaped plunger adapted to be forced longitudinally between the roller and the die-holder.

8. In a spike-machine, a bed-plate provided with side and end walls, the end wall being recessed, cutting mechanism adjacent to said recess, a stationary die bearing against one of the walls, a die-holder against the other wall, a die in said holder, and a wedge-shaped plunger, a removable point-forming block mounted in said die, the forward edge of which is adapted to be provided with notches, whereby the point of the spike may be provided upon its rear face with serrations.

9. In a spike-machine, a bed-plate provided with side and end walls, stationary die at one side of the plate, a die-block at the other side, a die in the block, the lower edge of which is slotted, a forming-block in said slot, a rod secured to said forming-block and projecting through the die-block, a spring on said rod, and means for forcing the die-block and the die toward the stationary die.

10. In a spike-machine, a bed-plate provided with side and end walls, cutting mechanism adjacent to the end wall, a stationary die bearing against one of the side walls, a block seated in the opposite side wall and provided with a roller, a screw through the side wall for engaging with said block, a die-block adjacent to said wall, a die in the block, and a wedge-shaped plunger adapted to be forced between the die-block and the roller.

11. In a spike-machine, a bed-plate provided with side walls, a stationary die-block resting against one of the walls, an adjustable roller-block mounted in the other wall, a die-block adjacent to said roller-block, a bolt through the side wall with its inner end secured in the die-block, a spring upon said bolt for normally forcing the die-block outward, and a wedge-shaped plunger adapted to be forced between the roller-block and the die-block.

12. In a spike-machine, a bed-plate provided with side walls, a stationary and a movable die mounted between said walls, grippers in said die adapted to be moved longitudinally thereof, and means for moving the movable die toward the stationary die.

13. In a spike-machine, a bed-plate provided with side walls, a stationary and a movable die between said walls, spring-actuated grippers mounted in said die to be moved longitudinally thereof, and means for simultaneously operating the grippers and moving the movable die toward the stationary die.

14. In a spike-machine, a bed-plate provided with side walls, a stationary and a movable die between said walls, the inner face of each of which is provided with an inclined wall recess, inclined grippers in said recesses, and adapted to be moved longitudinally of the die, means for limiting the movement of the grippers, and means for forcing the movable die toward the stationary die.

15. In a spike-machine, a bed-plate, dies mounted thereon, grippers in said dies arranged to be moved longitudinally thereof, a spring connected with each gripper, the outer end of which rests upon a fulcrum and an adjusting-screw upon each side of the fulcrum in position to engage with said spring.

16. In a spike-machine, a bed-plate provided with side walls, a stationary and a movable die between said walls, the stationary die being grooved longitudinally upon its outer edge, a link mounted in said groove, provided with point-forming means at one end, a forming-block in position to engage with the head of said link, and means for moving the link longitudinally, and for operating the movable die.

17. In a spike-machine, a bed-plate provided with side walls, a movable and a stationary die, the outer edge of the movable die being grooved longitudinally, a substantially L-shaped link mounted in said groove, the point of which is adapted to form the point of the spike, a forming-block in position to be engaged by the head of said link, and means for operating the movable die.

18. In a spike-machine, a bed-plate, dies mounted thereon, and a recessed header-block, movable toward and from the dies, and provided with a laterally-movable head-forming die, said die being angled and pivotally secured at one end within said recess.

19. In a spike-machine, a bed-plate, dies mounted thereon, a header-

black, the forward end of which is provided with a spring-supported, laterally-movable, hand-forming die.

20. In a spitz-machine, a bed-plate, die mounted thereon, a reciprocating header-block, an angled hand-forming die pivotally secured to said block at one end, the free end of which is recessed, a spring seated longitudinally within the block and in engagement with the die, and means for adjusting the tension of said spring.

21. In a spitz-machine, a bed-plate, die mounted thereon, a recessed die-block, a hand-forming die pivotally secured to the block at one end, and having its free end extended laterally in position to be forced against the head of the block, and a spring for normally forcing the free end of said die away from the block.

22. In a spitz-machine, a bed-plate, die thereon, a slotted header-block, a hand-forming die and a bar in said slot, a rod secured to the free end of the die and projecting through the bar, a spring upon the rod between the die and the bar, and slotted plates mounted upon the top and bottom of the header-block in position to engage with the bar and adjust the tension of the spring.

23. In a spitz-machine, a bed-plate, a stationary and a movable die thereon, a header-block at one end of the die, and cutting mechanism at the other, and means for simultaneously moving the blank through the dies longitudinally, and moving the movable die laterally, and withdrawing the header-block.

24. In a spitz-machine, a bed-plate the top of which is recessed and provided with integrally-formed side walls and spitz-forming mechanism upon the plate between the walls and so arranged that the strain upon the die in forming the spitz will fall upon the side walls, in combination with means for adjusting the die.

25. In a spitz-machine, a bed-plate, a stationary and laterally-movable die thereon, point-forming mechanism, a header and gripper adjustably secured in the walls of the die for moving the blank within the same.

698,101. FOLDING CARRIAGE. HENRIE BERNHARDT, New York, N. Y. Filed June 20, 1900. Renewed Jan. 20, 1902. Serial No. 91,748. (No model.)

Claim.—1. In folding carriages the combination of a full-board, a foot-rest and front-wheel brackets secured thereto, the full-board, together with the foot-rest, front-wheel brackets and front wheels attached thereto, capable of being folded inwardly and upwardly substantially in the manner and for the purpose set forth and shown.

2. In folding carriages—in combination with a full-board—a foot-rest and front-wheel brackets, secured thereto and capable of being folded inwardly and upwardly—slides and brackets having the rear wheels attached thereto by means of which the rear wheels may be adjusted longitudinally with the rest of the carriage, and the whole compactly folded, substantially in the manner and for the purpose set forth and shown.

3. The slide or wheel-brackets attached thereto, wheels attached to said brackets, and means for engaging said slide to prevent lateral motion thereof; all combined, arranged and operated substantially as shown and for the purpose described.

698,102. PROCESS OF MANUFACTURING IMPREGNATED MOUTH-PIECES. HARTLEY. GEORGE DUNHAM, Berlin, Germany. Filed June 20, 1901. Serial No. 91,546. (No specimens.)

Claim.—A process of manufacturing impregnated mouth-pieces, consisting in exposing the impregnated mouth to a flame, produced around the outer surface of a sleeve-body, corresponding in form and also to the desired form of the mouth, substantially as set forth.

698,103. SPEED-CHANGER. ERIC OBERHOLSER, Lynn, Mass., assignor of one-half to John W. A. Lumbard, Lynn, Mass. Filed Sept. 20, 1901. Serial No. 75,000. (No model.)

Claim.—1. A speed-changer comprising a rotary shaft, an eccentric carried thereby and held against rotation thereon and a second eccentric carried by said shaft and rotatable with relation thereto for changing the radial position of the first eccentric, and means for positively rotating said second eccentric.

2. A speed-changer comprising a rotary shaft, an eccentric carried thereby and non-rotatable thereon, a second eccentric carried by said shaft and rotatable thereon in engagement with said first eccentric, and a rack-and-pinion device for positively rotating said second eccentric, and means for operating said rack-and-pinion device independently of the rotation of said shaft.

3. A speed-changer comprising a rotary shaft, an eccentric rotatably mounted on said shaft, a second eccentric mounted on said first eccentric and within which said first eccentric is independently movable, an eccentric-strap mounted on said second eccentric, means connected therewith for transmitting motion, and means for positively moving said first eccentric independently of said shaft.

4. A speed-changer comprising a rotary shaft, two eccentrics mounted on one on the other and carried by said shaft, and means for rotating the inner eccentric independently of said shaft and of the other eccentric, said means including a gear carried by said shaft and connected with said inner eccentric and a rack and pinion for driving said gear, said rack being movable longitudinally of said shaft.

5. A speed-changer comprising a rotary shaft, two eccentrics mounted on one on the other and carried by said shaft, means permitting the outer eccentric to move outwardly and inwardly with relation to said shaft and requiring the shaft and said outer eccentric to rotate in unison, and means for rotating the inner eccentric independently of said shaft and of the other eccentric, said means including a gear carried by said shaft and connected with said inner eccentric and a rack and pinion for driving said gear, said rack being movable longitudinally of said shaft.

6. A speed-changer comprising a rotary shaft, two eccentrics mounted on one on the other and carried by said shaft, an arm extending from the outer eccentric, a hub and arm fixed on said shaft adjacent thereto, and a link connecting said two arms, and means for rotating the inner eccentric independently of said shaft and of the other eccentric.

698,104. MACHINE FOR CUTTING PREPARED SHEETS FOR AUTOMATIC MUSICAL INSTRUMENTS. NEWELL CLARK, Chicago, Ill. Filed May 2, 1900. Renewed Aug. 21, 1901. Serial No. 79,021. (No model.)

Claim.—1. In a music-perforating machine, an assembly of punches corresponding to longitudinal lines on which perforations are to be made; a carrier for the punches, and mechanism for actuating each carrier; punch-collectors, one for each punch, and means for actuating each collector; conductors corresponding to the notes, and a support for the terminals of each conductor; and a master-piece traveling over the terminals on each support and acting upon the terminals to control the notes.

2. In a music-perforating machine, an assembly of punches corresponding to longitudinal lines on which perforations are to be made; a carrier for the punches, and mechanism for actuating each carrier; punch-collectors, one for each punch, and means for actuating each collector; conductors from the notes and a terminal-support to which they lead; a master-piece traveling over the terminal-support acting upon the terminals to control the notes, each terminal-support being adjustable relatively to the master-piece in the direction of the travel of the latter.

3. In a music-perforating machine, an assembly of punches corresponding to all longitudinal lines on which perforations are to be made; a carrier for the punches and mechanism for actuating each carrier; punch-collectors, one for each punch, and means for actuating each collector; conductors from the notes and a terminal-support to which they lead; a master-piece traveling over the terminal-support acting upon the terminals to control the notes, each terminal-support being adjustable relatively to the master-piece in the direction of the travel of the latter.

4. In a music-perforating machine, an assembly of punches corresponding to all longitudinal lines on which perforations are to be made; a carrier for the punches and mechanism for actuating each carrier; punch-

collector, one for each punch, and mechanism for actuating the punch-collector; ducts from the pneumatic, and a mouthpiece-board to which they lead; a master-piece traveling over the mouthpiece-board for controlling the pneumatic, each mouthpiece-board being adjustable relatively to the master-piece in the line of travel thereof.

5. In combination with the punches and means for feeding the paper past them, the punch-collector and means which actuate them; conductors for the motive fluid and terminals for each conductor; a master-piece and suitable means for giving it travel, and fingers on the terminals respectively protruding against the master-piece and adapted to enter the apertures therein.

6. In combination with the punches and means for feeding the paper past them, the punch-collector and master-pneumatic which actuate them, and primary pneumatic which control the master-pneumatic; the mouthpiece-board and ducts therefrom to the primary pneumatic respectively automatically opening valves which close the mouths of each duct, and fingers carried by the valves and protruding against the master-piece, whereby the master-piece both the valves closed, each finger being adapted to enter the apertures in the master-piece to permit the valves to open.

7. In a perforating-machine which is controlled by a master-piece, the perforating-punches and devices which control their selection and action comprising motive-fluid conductors having terminals which are controlled by the master-piece; a two-part transposing-board, the conductors extending to one of said parts from the punch-controlling mechanism and to the other of said parts from the master-piece-controlled terminals, said conductors in said transposing-board members being all equally spaced and those of one member being adapted to register with those of the other, one member being movable with respect to the other to shift the registration of the conductors.

8. In a pneumatically-controlled perforating-machine, a two-part transposing-board; the primary pneumatic and ducts therefrom to one member of said board; a master-piece and a mouthpiece-board over which it travels, and ducts from the other member of the transposing-board to each mouthpiece-board, the ducts in said transposing-board members being all equally spaced, and those of one member being adapted to register with those of the other, one member being movable longitudinally with respect to the other to shift the registration of the ducts.

9. In a music-perforating machine, an assembly of punches corresponding to all longitudinal lines on which perforations are to be made, the carrier for the punches and mechanism for actuating it; a punch-collector for each punch, and device for actuating the punch-collector; the master-piece and connections therefrom to the punch-collector-actuating device respectively, adapted to bring said device into action upon the depression of corresponding keys of the manual respectively, and a master-piece-indicator mounted by the feeding and punch-actuating mechanism, whereby the operator may manipulate the manual in time with the feeding and punch-actuating movements of the machine.

10. In a music-perforating machine, in combination with the punches, and mechanism for actuating them, the punch-collector mechanism; a master-piece which controls the punch-collector mechanism; and a feeding device for each master-piece, the master-piece having lateral rows of feed-apertures and the feeding device having corresponding rows of tapered feed-pins, which at the base are of the full size of the feed-apertures of the master-piece; the apertures and pins being equally spaced on the master-piece and feed device respectively.

11. In a music-perforating machine, in combination with the punches and mechanism for actuating them, the punch-collector mechanism operated step by step synchronously with the punching mechanism, the master-piece being wider than the paper and provided with lateral rows of equally-spaced feed-apertures beyond the margins of the paper, the feeding device consisting of a belt wider than the paper and provided with lateral rows of taper-pointed feed-teeth spaced equally with the apertures of the master-piece, the paper and master-piece being both clamped to the feed-belt and simultaneously actuated thereby, the feed-teeth of the belt being adapted to enter and at their base to fill the apertures in the master-piece.

12. In a music-perforating machine, a master-piece provided with apertures having their dimensions in the direction of travel of the master-piece multiples of a certain minimum distance, plus a certain excess which is small relatively to said distance.

13. In a perforating-machine, the master-piece provided with apertures which control the action of the machine, whose dimensions in the direction of travel of the master-piece are multiples of a certain minimum distance plus a certain excess which is small relatively to said minimum distance, in combination with fingers adapted to enter the apertures, having their diameter, or dimension in the line of the master-piece travel, somewhat greater than said excess.

698,105. SUMMARY GOLD-SAVING DEVICE. LEO D. GRAM, San Francisco, Cal., assignor, by mesne assignments, to Robt. Harris Mining Company, San Francisco, Cal., a Corporation of California. Filed Apr. 14, 1902. Serial No. 12,519. (No model.)

Claim.—1. A submarine mining-machine, comprising an elongated open-ended sluice-box adapted to be dragged along a subaqueous bottom, means for operating the box, expelling means within the box, and wheels at the respective ends of the box, the forward wheels carrying a counter-weight higher plane than the rear wheels, substantially as described.

2. In a device for dredging, washing and expelling subaqueous material, the combination with an open trough, of a series of rollers arranged transversely therein, the rollers spaced within the trough above the rollers, a carrier carried by the trough for expelling the material during the movement of the trough and of means by which the trough is propelled.

698,106. BOX. STEVEN BALDWIN, Baltimore, Md. Filed July 18, 1901. Serial No. 68,468. (No model.)

Claim.—1. In a truss-down box, the combination of a collapsible body, and one or more foldable keepers therein; with a closure-wall having a latch portion suitably joined thereto and adapted precedent to use to rest in the plane thereof; said latch portion being also adapted to be disposed at an angle to the closure-wall, and arranged to enter between the walls of the body and spring into engagement with the keeper or keepers thereof.

2. In a box, the combination of a body having an interior keeper, and a closure-wall formed of pasteboard and having an angularly-disposed, integral latch at its edge adjacent to the keeper; the said latch being arranged to enter between the walls of the body and spring into engagement with the keeper thereof, substantially as specified.

3. In a box, the combination of a body having an interior keeper, the inner edge of which is inclined or beveled, and a closure-wall formed of pasteboard and having an angularly-disposed, integral latch at its edge adjacent to the keeper; the said latch being arranged to enter between the walls of the body, and spring into engagement with the beveled portion of the keeper, substantially as specified.

4. In a box, the combination of a body having interior keepers at two of its corners, and a closure-wall having an angularly-disposed, integral latch at its edge adjacent to the keepers; the said latch being arranged to enter between the walls of the body and having end portions adapted to engage the keepers thereof when the latch is released, substantially as specified.

5. In a box, the combination of a collapsible body, and one or more foldable keepers therein, with a closure-wall having a latch or latches arranged to enter the body and engage the keeper or keepers thereof, substantially as specified.

6. In a box, the combination of a collapsible body, and foldable keepers arranged therein and provided with beveled inner portions, with a closure-wall having an integral angularly-disposed latch arranged to enter between walls of the body and provided with end portions which it is adapted to carry into engagement with the beveled portions of the keepers, substantially as specified.

7. In a box, the combination of a collapsible body, formed of pasteboard, keepers disposed within the body at corners thereof, and arranged whereby they are adapted to be folded when the body is collapsed, and extend from the walls of the body when the same is opened, and a closure-wall also formed of pasteboard and having an inwardly-directed, integral latch, the ends of which are arranged to engage the keepers of the body, substantially as specified.

8. In a box, the combination of a collapsible body, the foldable keepers arranged in said body at the corners thereof, and the bottom and cover having integral, inwardly-directed latches, the ends of which are arranged to enter between walls of the body and engage with the foldable keepers thereof, substantially as specified.

698,107. AUTOMATIC RAPID-FIRE GUN. VICTOR P. DE KNIGHT, Washington, D. C. assignor, by direct and mesne assignments, to the Victor P. De Knight Gun Company, Washington, D. C., a Corporation of Delaware. Filed July 29, 1900. Renewed Oct. 29, 1900. Serial No. 34,598. (No model.)

Claim.—1. In a gun-operated rapid-fire gun, the combination of a receiver having a screw-threaded bore on its forward end, a barrel projecting from the receiver and supported thereby, a gas-conduit communicating with said barrel in the rear of its muzzle and extending back to the receiver, a water-jacket embracing said conduit and barrel and having a flanged inner end abutting the bore on the receiver, and a coupling-collar taking over the flange of the jacket and engaging the screw-thread of said bore.

2. In a gun-operated rapid-fire gun, the combination with the receiver, the barrel and the gas-conduit, of a water-jacket embracing said conduit and barrel and detachably coupled to the receiver and having lugs which engage opposite sides of the gas-conduit to hold the jacket from turning in either direction.

3. In a gun-operated rapid-fire gun, a gas-conduit communicating with the barrel at the forward part of the same and extending rearwardly therefrom, a cylinder compounded with said conduit, a perforated plug closing the rear end of the cylinder, a piston in said cylinder, and leading mechanism actuated by said piston.

4. In a gun-operated rapid-fire gun, the combination of a barrel having a screw-threaded socket on one side and a port through the bottom of said socket, a gas-conduit in the form of a pipe having a transversely-

apertured and interiorly-screw-threaded head, a plug screwing into said head and into the socket of the barrel and having a bore communicating with the port in the bottom of said socket and also having a part to register with the pipe-bore, a cylinder compounded with said pipe, a piston in said cylinder, and leading mechanism actuated by said piston.

5. In a gun-operated rapid-fire gun, the combination of a barrel having a screw-threaded socket on one side and a port through the bottom of said socket, a gas-conduit in the form of a pipe having a transversely-apertured and interiorly-screw-threaded head, a plug screwing into said head and into the socket of the barrel and also having a part to register with the pipe-bore, a valve or stopper in the form of a screw entered through one side of the pipe-head and having an end portion protruding into the bore of the plug, a cylinder compounded with the said pipe, a piston in said cylinder, and leading mechanism actuated by said piston.

6. In a rapid-fire gun, the combination of a reciprocating actuator having a laterally-projecting cam-lug tapering as it extends forward, a horizontally-vibratory lever arranged laterally beyond the said cam-lug and having a roller to coast therewith in effecting outward movement of the lever under forward movement of the actuator, and a cartridge-feeding slide coupled to said lever and equipped with dogs adapted to successively engage cartridges carried in a belt which passes through the receiver of the gun, provision existing by virtue of which the lever and slide are actuated when the actuator moves rearwardly, substantially as described.

7. In a rapid-fire gun, the combination of a reciprocating actuator having a laterally-projecting cam-lug tapering as it extends forward, a horizontally-vibratory lever arranged laterally beyond the said cam-lug and having a roller to coast therewith in effecting outward movement of the lever under forward movement of the actuator, and a cartridge-feeding slide coupled to said lever and equipped with dogs adapted to successively engage cartridges carried in a belt which passes through the receiver of the gun, together with a spring arranged to retract the lever and slide upon rearward movement of the actuator.

8. In a rapid-fire gun, a receiver having openings in opposite sides and a passage-way between said openings, one of the latter being of sufficient width to pass a cartridge crosswise and the other being of less width and the receiver having internal shoulders at opposite sides of the passage-way for the cartridge to abut, an upward-pointing pin standing out from the face of one of said shoulders, means for feeding a cartridge against the shoulders and under said pin, and means for removing the cartridge lengthwise from its position against the shoulders.

9. In a rapid-fire gun, the combination of a receiver, a reciprocating actuator therein having a cam-piece on one side and a roller on the opposite side running along a wall of the receiver, and cartridge-feeding device cooperating with said cam-piece to advance a belt of cartridges step by step under retraction of the said actuator.

10. In a rapid-fire gun, the combination of a reciprocating actuator carrying a pair of extractor-fingers transversely disposed relative thereto, spring-pressed toward each other, movable in a plane substantially at right angles to the plane of movement of the actuator, and having oppositely-inclined confronting side faces adapted to encounter a cartridge-head in the feed-throat under one direction of movement of the actuator, longitudinal edges of said fingers snapping past the flange of the cartridge and extracting the latter from the throat upon the reverse movement of said actuator; and means for feeding cartridges into the throat.

11. In a rapid-fire gun, the combination of a reciprocating actuator carrying a pair of extractor-fingers spring-pressed toward each other and having oppositely-inclined confronting faces adapted to encounter a cartridge-head in the feed-throat under one direction of movement of the actuator, said fingers snapping by the flange of the cartridge and extracting the latter from the throat upon the reverse movement of said actuator, and having lugs on their rear edges to hold the cartridge down; and means for feeding cartridges into the throat.

12. In a rapid-fire gun, the combination of a receiver having a cartridge-belt passage extending transversely through its front portion and a throat to receive the cartridges one by one, an upward-pointing guard-pin standing out toward the entrance to the throat at one side of the throat and holding a cartridge in proper position therein, a reciprocating actuator having means for extracting the cartridge from the belt, and means for feeding the cartridges into the throat.

13. In a rapid-fire gun, the combination of a receiver having a feed-throat, means for feeding cartridges crosswise into said throat, a reciprocating actuator having a block recessed in its side and across its top, fingers pivoted in the side recess and having depending portions with oppositely-inclined confronting faces, and a spring in the top recess of the block bearing upon the upper ends of the fingers and pressing their depending portions toward each other, the confronting faces of the latter adapted to encounter the flanged head of the cartridge in the throat where by the fingers are spread apart and snap over the flange of the cartridge, substantially as and for the purpose described.

14. In a rapid-fire gun, the combination of a receiver having a throat for cartridges, a reciprocating actuator having means for extracting the cartridge from said throat, a cartridge-depressing and pointing arm normally standing on an upward inclination and beneath which arm the cartridge is carried by the extracting means, and means carried by the reciprocating actuator for depressing said arm upon the advance of the actuator, substantially as and for the purpose described.

15. In a rapid-fire gun, the combination of a receiver having a throat for cartridges, a reciprocating actuator having means for extracting the cartridge from said throat, a cartridge-depressing and pointing arm normally standing on an upward inclination and beneath which arm the cartridge is carried by the extracting means, said arm having an upstanding lug, and a laterally-movable spring-pressed wiper on the reciprocating actuator positioned to encounter said lug with one side edge in the rearward stroke of the actuator and to thereby displace and to encounter the lug with its forward end in the advance of the actuator thereby depressing the arm, substantially as and for the purpose described.

16. In a rapid-fire gun, the combination of a receiver having a cartridge-throat at its forward part, a reciprocating actuator having means for extracting a cartridge from the throat, a breech-block engaged with said actuator so as to be retracted thereby and grooved in its upper side at the throat, a cartridge-depressing and pointing arm pivoted to a stationary support and having a heel-piece engaging the breech-block whereby when the latter is advanced the arm is held in an upward-inclined position where the cartridge can pass under it, and when the breech-block is retracted said arm may drop by reason of the groove in the breech-block receiving the heel-piece of the arm; and means carried by the actuator for throwing down the said arm, substantially as and for the purpose described.

17. In a rapid-fire gun, the combination of a receiver having a feed-throat at its forward part, a reciprocating actuator having spring-pressed fingers to catch a cartridge in said throat, a pivoted arm standing normally in an upward-inclined position where the said spring-fingers will pass on either side of it when the actuator moves rearwardly, and means carried by the actuator for depressing said arm when said actuator advances and the cartridge has been delivered under the arm.

18. In a rapid-fire gun, the combination of a receiver having a throat for cartridges, a reciprocating actuator having means for extracting the cartridge from said throat, a cartridge-depressing and pointing arm normally standing on an upward inclination and beneath which arm the cartridge is carried by the extracting means, means carried by the reciprocating actuator for depressing said arm upon the advance of the actuator, a lower cartridge-pointing arm or lever, and means for elevating the latter to receive the ball end of the cartridge.

19. In a rapid-fire gun, the combination of a receiver having a throat for cartridges, a reciprocating actuator having means for extracting the

cartridge from said throat, a cartridge-depressing and pointing arm normally standing on an upward inclination and beneath which arm the cartridge is carried by the extracting means, means carried by the reciprocating actuator for depressing said arm upon the advance of the actuator, a lower cartridge-pointing arm or lever, and a breech-block engaged with the actuator so as to be retracted thereby and grooved in the under side to receive the heel of said lower cartridge-pointing lever, the forward end of said groove opening on the backward movement of the breech-block to tilt the said lever to position for receiving the ball end of the cartridge, substantially as and for the purpose described.

20. In a rapid-fire gun, the combination of a receiver having a cartridge-throat at its forward part, a reciprocating actuator having means for extracting a cartridge from the throat, a breech-block engaged with said actuator so as to be retracted thereby and grooved in its upper and lower sides, upper and lower cartridge-pointing arms having heels for engagement with said grooves respectively, the breech-block in its forward position holding the lower arm depressed, and the upper arm elevated so that the cartridge can pass under it, and means carried by the actuator for depressing the upper arm on the forward stroke of the actuator, an accompanying forward movement of the breech-block causing the front end of its lower groove to elevate the cartridge-receiving end of the lower arm.

21. In a rapid-fire gun, the combination of a receiver having a feed-throat at its forward part, a reciprocating actuator having means for extracting cartridges one by one from said throat, a breech-block engaged with the actuator so as to be retracted thereby, means for delivering the cartridge in front of the said breech-block, a guide or pointing-lever to receive the ball end of the cartridge when so delivered, and means for shifting said lever, substantially as described.

22. In a rapid-fire gun, the combination of a receiver having a feed-throat at its forward part, a reciprocating actuator having means for extracting cartridges one by one from said throat, a breech-block engaged with the actuator so as to be retracted thereby, and grooved in its under side, means for delivering the cartridge in front of said breech-block, and a pointing-lever having a heel to receive the ball end of the cartridge when so delivered and having a heel to enter the groove in the under side of the breech-block, the forward end of said groove opening to tilt the lever and bring its heel up into position for receiving the ball end of the cartridge.

23. In a rapid-fire gun, the combination of a receiver having a discharge-opening in one side, a grooved breech-block repressing in said receiver and past said opening, spring-pressed extractor-fingers in grooves of said breech-block, one located in a lower plane than the other, and having a cam projection, an abutment in the receiver for said cam projection to encounter, and an ejector on the receiver and projecting into a groove in the breech-block where the extracted shell will encounter it upon being disengaged from the catch having the cam projection.

24. In a rapid-fire gun, the combination of a receiver having a chamber running back from the barrel and a discharge-opening in one side of the chamber, a breech-block in said chamber, spring-pressed extractor-fingers carried by the breech-block, one located in a lower plane than the other, means for tripping that one of said catches, an ejector abutment for the cartridge to encounter upon disengagement from said catch, and means for repressing the breech-block.

25. In a rapid-fire gun, the combination of a reciprocating breech-block, arranged to be moved backward by force resulting from a discharge, a spring arranged to impel said breech-block forward, a firing-pin in the breech-block, a hammer carried by the breech-block and spring-actuated into engagement with the firing-pin, a lever arranged to engage said hammer and hold it while the breech-block moves forward, a latch arranged to lock the breech-block in its forward position, means for automatically displacing said latch, and trigger mechanism for tripping the lever and establishing a connection between the latter and the latch, substantially as described.

26. In a rapid-fire gun, a reciprocating structure adapted to be actuated in one direction by force resulting from a discharge and in the opposite direction by spring-pressure, said structure comprising a member receiving the direct impact of the returning force and having abutment-pieces and a cam-piece, a breech-block having a part extending between the said abutment-pieces, a sufficient space being provided to permit movement of the said member having the abutment-pieces independent of the breech-block, a firing-pin in the breech-block, and a hammer carried by the latter and spring-actuated toward the firing-pin; in combination with a lever adapted to engage said hammer and hold it while the breech-block advances, a latch arranged to lock the breech-block in its forward position and adapted to be displaced by the cam-piece on the first-mentioned member of the reciprocating structure, and trigger mechanism for tripping the lever and establishing a connection between the same and the latch, substantially as described.

27. In a gun-operated gun, the combination of a reciprocating actuator, a breech-block engaged therewith, a spring-pressed hammer carried

by the breech-block, a locking-piece in the form of an automatic catch operating independently of the actuator-reciprocating means and adapted to hold the breech-block against the breech end of the gun-barrel; a cam, and connections between the locking-piece and cam whereby the latter is tripped by the movement of the former into locking position.

28. In a gas-operated gun, the combination of a reciprocating actuator, a breech-block engaged therewith, a spring-pressed hammer carried by the breech-block, a locking-piece in the form of a spring-pressed catch for holding the latter against the breech end of the gun-barrel, a cam, and connections between the locking-piece and cam whereby the latter is tripped by the movement of the former into locking position.

29. In a gas-operated gun, the combination of a reciprocating actuator, a breech-block engaged therewith, a spring-pressed hammer carried by the breech-block, a locking-piece for holding the latter against the breech end of the gun-barrel, a cam, and trigger mechanism establishing a connection between the lock and cam whereby the latter is tripped by movement of the former into locking position.

30. In a gas-operated gun, the combination of a breech-block, a spring-pressed hammer carried thereby, a locking-lever spring-pressed to locking engagement with the breech-block and having a heel a cam pivoted concentrically with said lock-lever and having a heel confronting that of the latter, said cam being pressed to hammer-engaging position by a spring inferior to that which actuates the locking-lever, a filter-piece or wedge between said confronting heels, manipulative means connected with said wedge, a reciprocating actuator engaged with the breech-block but movable a distance independently thereof and having a projection to act against the cam protuberance of the locking-lever, substantially as and for the purpose described.

31. In a gas-operated gun, the combination of a breech-block, a spring-pressed hammer carried thereby, a locking-lever spring-pressed to locking engagement with the breech-block and having a heel, and a cam protuberance, a cam pivoted concentrically with said lock-lever and having a heel confronting that of the latter, said cam being pressed to hammer-engaging position by a spring inferior to that which actuates the locking-lever, a filter-piece or wedge between said confronting heels, manipulative means connected with said wedge, and a reciprocating actuator engaged with the breech-block but movable a distance independently thereof and having a projection to act against the cam protuberance of the locking-lever, substantially as and for the purpose described.

32. In an automatic rapid-fire gun, a reciprocating actuator having a bifurcated arm, and a slide-rod having a head and a head to abut the front side of the bifurcated arm and a cross-piece to abut the rear side of said bifurcated arm when the rod is turned, substantially as described.

33. In a rapid-fire gun, the combination of a receiver having a transverse passage for a belt of cartridges and a throat to receive the cartridges one by one, while in the belt, a feed-slide having dogs arranged to move a cartridge into the throat by opening against a cartridge further removed from the throat, means for reciprocating the slide, and means for extracting from the belt the cartridge in the throat.

34. In a rapid-fire gun, the combination of a reciprocating actuator having a bifurcated arm, a manipulative slide-rod extending through said bifurcation and having a head to encounter one side of the arm, said rod also having a cross-piece of dimensions to pass through the bifurcation under one adjustment of the rod and to take over the side of the bifurcation opposite that which the head abuts, when the rod is turned to another adjustment; and cartridge feeding, loading, firing and extracting means in operative connection with the actuator.

35. In a rapid-fire machine-gun, the receiver having the longitudinally-disposed ribs or guides on opposite sides thereof, in combination with the interspersed reciprocating bar bearing against said guides and having bifurcated portions embracing the same; said bar having a forward extension and cam portions thereon for engaging and actuating the feed-slide-actuating lever, and also provided with means for actuating the cartridge-depressing arm, the breech-block lock, and breech-block, and with means for extracting a cartridge from the cartridge-belt when the actuator means forward, substantially as described.

698,108. **SAFETY DEVICE FOR PISTOL-BATTERY.** LAURENCE B. BROWN, Minneapolis, Minn. Filed Dec. 14, 1906. Serial No. 58,888. (No model.)

Claim.—1. In a switch, the combination, with the movable points, of a filling-piece secured to the outer side of one of said points, and means independent of said point for limiting the lateral movement of the other point, substantially as described.

2. In a switch, the combination, with the movable points arranged to permit the wheels to pass outside of both points when the switch is partially open or in a neutral position, of a filling-piece secured to the outside of one point and adapted to receive and support the flange of the wheel, and means independent of said point for limiting the lateral movement of the other point, whereby the wheels on that side of the track are kept in position upon the rail, for the purpose set forth.

3. The combination, with the stock-rail, and the rail of the main and the side tracks, of the movable points, one of said movable points being provided with a filling-piece secured to its outer side and rigid means independent of said point for limiting the lateral movement of the other point, and means for guiding the wheels back onto the main track, for the purpose set forth.

4. The combination, with the rail of the main and side tracks, of the movable points arranged to permit the wheels to pass outside of both points when the switch is partially open or in a neutral position, and means permitting one of said points to be forced laterally toward the other point upon the passage of a train when the switch is partially open, for the purpose set forth.

5. The combination, with the rail of the main and side tracks, of the movable points arranged to permit the wheels to pass outside of both points when the switch is partially open, or in a neutral position, means limiting the forward lateral movement of one of said points, and means permitting an inward or lateral flexing of the other point, for the purpose set forth.

6. The combination, with the rail 2, of the movable point 10 provided with the axle 22, carrying the plunger 23, and the stop-collar 26 for the purpose set forth.

7. The combination, with the rail 2, of the movable point 10, provided with the axle 22 having the hook 25, and the plunger 23, for the purpose set forth.

8. The combination, with the rail 2, of the movable point 10, provided with the axle 22, having a suitable hook 25, and the dotted plate 29 provided with the lip 30, for the purpose set forth.

9. The combination, with the movable point 10, of the cylinder 16, provided with the spring 17, the follower 18 and the bell or rod 19 extending through said follower and spring and connecting with the point 10, said spring being adapted to move said point away from the rail of the main track or out of side-track position, substantially as described.

10. The combination, with the movable points and the right hand-rail, of the dotted bridge-rod connecting said points, for the purpose set forth.

11. The combination, with the rail of the main and side tracks, of a movable switch-point adapted, when brought against one of the main rails, to connect said rail with the adjacent side-track rail and means, connected with said point and adapted to normally hold said point out of contact with said main rail and in a neutral position, for the purpose set forth.

12. The combination, with the rail of the main and side tracks of the movable switch-point and means for holding the side-track point out of engagement with the main-track rail and in a neutral position.

13. The combination, with the stock-rail 3 and 4, of the movable

points 10 and 11 and means for holding the point 10 normally out of engagement with the stock-rail 3 and in a neutral position, for the purpose set forth.

14. The combination, with the stock-rail 3 and 4 of the movable points 10 and 11 and a spring device connected with the point 10, and adapted to hold said point normally out of engagement with the stock-rail 3 and in a neutral position, for the purpose set forth.

698,109. **EXHAUSTING APPARATUS.** BERNARD FROSTEN. Paris, France. Filed Feb. 2, 1906. Serial No. 604,963. (No model.)

Claim.—1. In an apparatus for use as described, the combination with a closed receptacle adapted to contain chlorinated and alkaline water, and an inner closed vessel adapted to contain disinfecting solution, of an extension containing two passages one communicating with the inner and the other with the outer receptacle, a rotatable plug having two lugs adapted to cooperate with said passages as described, a tubular extension having two branches which communicate at one end with the said passages and which merge at the opposite end into a single branch of the said tubular extension, and a diffusing or spraying device in communication with the said single branch of the tubular extension.

2. In an apparatus for use as described, the combination with an outer hermetically-closable receptacle and an inner closed receptacle, of an extension F having passages J, K, the cock L, the tubular extension comprising the branches I, M, N, the casing O, flexible extension R, and a spraying device connected with the latter extension, all as and for the purpose specified.

698,110. **WHEEL FOR ROLLER-SKATES.** ALFRED L. FAY. New York, N. Y. Filed Feb. 27, 1908. Serial No. 64,807. (No model.)

Claim.—1. The combination with a wheel or roller provided with a central opening, the outer ends of which are beveled, of an elastic sleeve fitted in said opening, key-pieces fitting in said elastic sleeve and having their outer ends beveled to correspond with the beveled ends of the opening in said roller and a metallic sleeve or cylinder extending through said key-pieces and adapted to lock the several parts in their proper relative positions, substantially as described.

2. The combination with a wooden roller provided with a peripheral groove and with a central opening, the ends of the latter being beveled, of a rubber sleeve fitted in said central opening, metallic key-pieces, the

body of each of which is cylindrical in form and the outer end beveled, whereby said rubber sleeve is secured, its entire length is tightly bound between said key-pieces and the wall of said central opening, and a metallic sleeve or bearing extending through said key-pieces and having its ends beveled slightly apart, whereby the several parts are firmly locked in their proper relative positions, substantially as described.

698,111. **MACHINE FOR EDGING AND MATCHING LUMBER.** HENRY A. GALT, Hartford, Conn., assignor to George W. Galt, Hartford, Conn. Filed Dec. 18, 1906. Serial No. 58,574. (No model.)

Claim.—1. A machine for edging and matching lumber consisting of a frame, a shaft supported horizontally near each end of the frame, means for rotating the shafts, two sprocket-wheels mounted upon each shaft, one of which wheels is fixed and the other is loose upon its shaft, an endless chain passing from shaft to shaft and connecting the fixed wheel on one shaft with the loose wheel on the other shaft, a lumber-feeding table connected with each of the oppositely-moving endless chains, a horizontal arbor supported by the frame near each end, means for rotating each horizontal arbor, a vertically-rotatable saw extending above and below the plane of the movable tables mounted upon diagonally opposite ends of each horizontal arbor outside of the frame, means for rotating each vertical arbor, a horizontally-rotatable cutter-head mounted upon the upper end of each vertical arbor and extending above the plane of the movable tables on diagonally opposite sides of the frame, and yielding means for holding the lumber down while each supporting-table carries it to a vertically-rotating saw and horizontally-rotating cutter-head, substantially as specified.

2. A machine for edging and matching lumber consisting of a frame, a shaft supported horizontally near each end of the frame, means for rotating the shafts, two sprocket-wheels mounted upon each shaft, one of which wheels is fixed and the other is loose upon its shaft, an endless chain passing from shaft to shaft and connecting the fixed wheel on one shaft with the loose wheel on the other shaft, a lumber-feeding table connected with each of the oppositely-moving endless chains, a horizontal arbor supported by the frame near each end, means for rotating each horizontal arbor, a vertically-rotatable saw extending above and below the plane of the movable tables mounted upon diagonally opposite ends of each horizontal arbor outside of the frame, means for rotating each vertical arbor, a horizontally-rotatable cutter-head mounted upon the upper end of each vertical arbor and extending above the plane of the movable tables on diagonally opposite sides of the frame, rolls loosely held by supports

above the table, and weighted levers for depressing the rolls and holding the lumber down while each supporting-table carries it to a vertically-rotating saw and horizontally-rotating outer-head, substantially as specified.

3. A machine for engaging and matching lumber consisting of a frame, a shaft supported horizontally near each end of the frame, means for rotating the shafts, two sprocket-wheels mounted upon each shaft, one of which wheels is fixed and the other is loose upon its shaft, an endless chain passing from shaft to shaft and connecting the fixed wheel on one shaft with the loose wheel on the other shaft, a lumber-feeding table connected with each of the oppositely-moving endless chains, a horizontal arbor supported by the frame near each end, means for rotating each horizontal arbor, a vertically-rotatable saw extending above and below the plane of the movable tables mounted upon diagonally opposite ends of each horizontal arbor outside of the frame, a vertical arbor near each end on opposite sides outside of the frame, means for rotating each vertical arbor, a horizontally-rotatable outer-head mounted upon the upper end of each vertical arbor and extending above the plane of the movable tables on diagonally opposite sides of the frame, rolls loosely held by supports above the table, springs for depressing the rolls, and weighted levers for depressing the springs, and holding the lumber down while each supporting-table carries it to a vertically-rotating saw and horizontally-rotating outer-head, substantially as specified.

698,112. FRITTON-GLAYTON. JAMES HALL, Radcliffe, England.
Filed Sept. 19, 1901. Serial No. 74,947. (No model.)

Claim.—In a friction clutch or coupling the combination with the shaft *a* and shaft *d* loose thereon of the fixed hub *p* firmly keyed to the shaft *a*; the disk *b* formed with correspondingly-grooved central openings to slide longitudinally thereon; the friction-disk *f* with projections *g* to engage corresponding recesses in the shaft *d* and arranged alternately with the disk *b* the ring *j*; the screw *s* to force the ring *f* against the disk *b* and *f* to bring them into frictional contact, the lever-wheel *u* and nut *v* to reciprocate the screw *s* the collar *y* to secure them in position the spindle *t* and lever-wheel *u* to gear with the lever-wheel *u*, the levers *c* with internal teeth *2* engaging similar teeth on the spindle *t* to rotate it; the nut *3* to hold the levers *c* in position, the connecting-rods *r* and sliding sleeve *l* to actuate the levers *c* substantially as described.

698,118. COUPLING-WELDING ROLL. RAYMOND H. HALL, McKeenport, Pa., assignor to National Tube Company, Pittsburgh, Pa., a Corporation of New Jersey. Filed Aug. 30, 1901. Serial No. 73,884. (No model.)

Claim.—1. A roll for forming pipe-couplings and similar articles provided with a plurality of working faces each corresponding to a finished coupling and an annular projection or projections intermediate the working faces for dividing the blank and finishing the end faces of the couplings, said roll having each end flange and the contiguous working faces formed in one piece, and the remaining working faces and annular ribs or projections formed in separate sections interposed between the end sections, means for rotating said sections together, and pins passing through the annular ribs-sections and having their ends seated in the working-face sections in lock said sections together.

separate from the other parts of the roll, and means for securing said sections together.

2. A roll for forming pipe-couplings and similar articles, provided with a plurality of working faces each corresponding to a finished coupling and an annular projection or projections intermediate the working faces for dividing the blank and finishing the end faces of the couplings, said roll having each end flange and the contiguous working faces formed in one piece, and the remaining working faces and annular ribs or projections formed in separate sections interposed between the end sections, and means for locking said sections together.

3. A roll for forming pipe-couplings and similar articles, provided with a plurality of working faces each corresponding to a finished coupling and an annular projection or projections intermediate the working faces for dividing the blank and finishing the end faces of the couplings, said roll having one end flange and the contiguous working faces formed in one section which has integral therewith a wobble and an axial core or projection, the other end flange and its contiguous working faces being formed as a sleeve adapted to surround the axial projection or core, and the annular projection being formed on a separate ring which is interposed between the end sections, and means for locking said parts together.

4. A roll for forming pipe-couplings and similar articles, provided with a plurality of working faces each corresponding to a finished coupling and an annular projection or projections intermediate the working faces for separating the blank and finishing the end faces of the couplings, said roll having each end flange and the contiguous working faces formed in one section and the remaining working faces and annular projection or projections formed in separate sections interposed between the end sections, means for securing said sections together, and pins passing through the annular ribs-sections and having their ends seated in the working-face sections in lock said sections together.

698,114. MACHINE FOR TRACKING TYPE-WRITING. FRANK REEZE, New York, N. Y. Filed July 16, 1901. Serial No. 67,708. (No model.)

Claim.—1. In a machine for tracking type-writing, the combination of a series of keys with a series of sign-carriers operatively connected thereto, and with a sign-sheet adapted to receive each carrier, substantially as specified.

2. In a machine for tracking type-writing, the combination of a series of keys with a series of sign-carriers operatively connected thereto, and with a sign-sheet adapted to receive each carrier, and simultaneously raise the keys, substantially as specified.

3. In a machine for tracking type-writing the combination of a series of keys with sign-carriers operatively connected thereto, a movable perforated sign-sheet adapted to receive each carrier, and signs displayed upon the carrier, substantially as specified.

4. In a machine for tracking type-writing the combination of a series of keys with sign-carriers operatively connected thereto, a movable perforated sign-sheet adapted to receive each carrier, and signs displayed upon the carrier, substantially as specified.

ries of keys with sign-carriers operatively connected thereto, a movable perforated sign-sheet adapted to receive each carrier, signs upon the carrier, and a shield that partly conceals each sign, substantially as specified.

5. In a machine for tracking type-writing the combination of a series of keys with a series of sign-carriers operatively connected thereto, a sign-sheet adapted to receive the signs, and with means for feeding each sign-sheet, substantially as specified.

6. In a machine for tracking type-writing, the combination of a series of sign-carriers with a sign-sheet adapted to receive the signs, means for feeding the sign-sheet, and a shield that partly conceals the signs, substantially as specified.

7. In a machine for tracking type-writing the combination of a series of sign-carriers with a sign-sheet adapted to receive the signs, means for feeding the sign-sheet, a shield adapted to partly conceal the signs, and a chamber for covering up the signs within or beyond the shield, substantially as specified.

8. In a machine for tracking type-writing, the combination of a cylindrical perforated sign-sheet with a series of sign-carriers adapted to be actuated by said sheet and with keys operatively connected in said sign-carriers, substantially as specified.

9. In a machine for tracking type-writing, the combination of a series of sign-carriers with keys operatively connected thereto and a cylindrical perforated sign-sheet adapted to receive the sign-carriers, substantially as specified.

10. In a machine for tracking type-writing the combination of a series of key-operated sign-carriers with an oscillating frame and a cylindrical sign-sheet carried by such frame and adapted to receive the sign-carriers, substantially as specified.

11. In a machine for tracking type-writing, the combination of a series of key-operated sign-carriers with a reel, means for rotating said reel, and a cylindrical sign-sheet removably secured to said reel, substantially as specified.

12. In a machine for tracking type-writing, the combination of a series of key-operated sign-carriers with a reel, means for rotating said reel, a cylindrical sign-sheet secured to said reel, and a stop for limiting the rotation of said reel, substantially as specified.

13. In a machine for tracking type-writing, the combination of a series of sign-carriers with a pair of telescopic perforated sign-sheets and means for changing the relative positions of said sheets, substantially as specified.

14. In a machine for tracking type-writing, the combination of a series of key-operated sign-carriers with a reel, a pair of telescopic cylindrical sign-sheets mounted upon said reel, means for changing the relative position of the sign-sheets, means for rotating the reel and means for limiting said rotation, substantially as specified.

15. In a machine for tracking type-writing, the combination of a pair of perforated telescopic sign-sheets with a series of sign-carriers adapted to be actuated thereby so as to raise or lower the signs on said carrier, substantially as specified.

16. In a machine for tracking type-writing, the combination of a series of key-operated sign-carriers with an oscillating frame, a rotatable sign-sheet supported thereby, and a stop-bar for limiting the movement of the sign-carriers when said sign-carriers are raised, substantially as specified.

698,115. MOLD FOR THE MANUFACTURE OF CELLULAR CUSHION-TIRES FOR WHEELS OF RAILROAD OR OTHER VEHICLES. CHARLES REED, Wrentham, R. I. Filed Sept. 11, 1901. Serial No. 73,080. (No model.)

Claim.—1. The improved mold for the manufacture of cellular cushion-tires, consisting of a plurality of longitudinal blocks, a set comprising a plurality of matrix-pieces mounted movably on and supported by each of said blocks, means for holding the matrix-pieces in their companion block, and means for holding said blocks together, substantially as described.

2. The improved mold for the manufacture of cellular cushion-tires, consisting of a plurality of grooved longitudinal blocks, a set comprising a plurality of matrix-pieces mounted on each of said blocks and movable in the groove thereof, means for holding the matrix-pieces adjustably in their companion block, and means for holding said blocks together, substantially as specified.

3. The improved mold for the manufacture of cellular cushion-tires, consisting of a plurality of supporting-blocks each of which has a longitudinal dovetailed mortise, a set comprising a plurality of matrix-pieces each of which has a dovetailed tenon engageable and movable in said mortise, means for holding the matrix-pieces in adjusted position in the mortise of their companion blocks, respectively, and means for holding said supporting-blocks together, substantially as described.

4. The improved mold for the manufacture of cellular cushion-tires, consisting of a plurality of supporting-blocks each of which has a longitudinal dovetailed mortise, a set comprising a plurality of matrix-pieces each of which has a dovetailed tenon engageable and movable in said mortise, a holding-plate on the ends of each supporting-block secured thereto, and means for holding said supporting-block together, substantially as shown.

5. The improved mold for the manufacture of cellular cushion-tires, consisting of three supporting-blocks each of which has a central, longitudinally-extending, dovetailed mortise, one of which blocks has a longitudinal projecting key and another of which blocks has a longitudinal groove with which said key is engageable and the third of which blocks fits over and embraces the tops of said first and second blocks, a set for each of said blocks comprising a plurality of matrix-pieces each of which has a dovetailed tenon engageable with the mortise of the companion block and a plate closing each end of each of said mortises, substantially as set forth.

6. The improved mold for the manufacture of cellular cushion-tires, consisting of three supporting-blocks each of which has a central longitudinally-extending, dovetailed mortise, one of which blocks has a longitudinal projecting key, the second of which blocks has a longitudinal groove with which said key is engageable and the third of which blocks fits over and embraces the tops of said first and second blocks, a set for each of said blocks comprising a plurality of matrix-pieces each of which has a dovetailed tenon engageable with the mortise of the companion block, a plate closing each end of each of said mortises, and a frame adapted to receive and hold the first and second of said supporting-blocks, together with means for clamping said frame to the two blocks just above, substantially as described.

7. In a mold for the manufacture of cellular cushion-tires, the combination of a mold-section having a longitudinal groove, a plurality of matrix-pieces adjustably mounted and held in said longitudinal groove and each having an upper concave end formed in the arc of a circle of a certain radius, and a plurality of other matrix-pieces adjustably mounted and held in said longitudinal groove and each having an upper concave end formed in an arc of a circle of a radius less than that of the arc first mentioned and also having radial slots extending from the last-mentioned concave end, said matrix-pieces respectively of this first set alternating with and in contact with said matrix-pieces, respectively, of the second set, substantially as and for the purpose specified.

8. In a mold for the manufacture of cellular cushion-tires, the combination of three mold-sections, each having a longitudinal groove, a set for each of said mold-sections comprising a plurality of matrix-pieces adjustably mounted and held in said longitudinal groove and each having a concave end formed in the arc of a circle one hundred and twenty degrees in extent and of a certain radius, and a set for each of said mold-sections comprising a plurality of matrix-pieces adjustably mounted and held in said longitudinal groove and each having a concave end formed in the arc of a circle one hundred and twenty degrees in extent and having a radius less than that of the arc first mentioned and also having radial slots extending from the last-mentioned concave end, said matrix-pieces of the first set alternating with and in contact with said matrix-pieces, respectively, of the second set, and means for holding said mold-sections in operative contact, substantially as specified.

9. In a mold for the manufacture of cellular cushion-tires, a matrix composed of detachable and adjustable plates extending in juxtaposition vertically in planes at right angles to the axial plane of the mold, the inner edges of said plates and the surfaces of said plates contiguous to said edges constituting the molding-surfaces of the matrix, substantially as described.

10. In a mold for the manufacture of cellular cushion-tires, a matrix composed of two sets of detachable and adjustable plates extending in planes at right angles with the axial plane of the mold, one set of said plates having when assembled a central circular aperture of a certain diameter and the other set of said plates having when assembled a central circular aperture of a less diameter from which extend radial slots, said sets being arranged with one of the plates of the first set in alternation with

and in contact with one of the plates of the second sort is a series the entire length of the mold, substantially as specified.

11. The improved mold for the manufacture of cellular cushion-tires herein described, consisting of the combination of the supporting-blocks A, B and C each having angular faces as shown and fitting together on their contiguous faces, each of which blocks has an inwardly-flaring longitudinal groove opening into a dovetailed mortise, a spline connection between the blocks A and B, the frame F having the screw-clamping ends J and adapted to fasten the blocks A and B together, a set of matrix-plates D for each of the blocks A, B and C and each having a dovetailed tenon, engageable with the mortise of its companion block and each having a concave end in an arc comprising one-third of a circle of a certain diameter, a set of matrix-plates E for each of the blocks A, B and C and each having a dovetailed tenon engageable with the mortise of its companion block and each having a concave end in an arc comprising one-third of a circle of a less diameter than the first-named circle, said matrix-plates D, respectively, being in contact with said matrix-plates E, respectively, and holding-plates closing the ends of said mortises, respectively, all arranged substantially as shown and for the purpose specified.

698,116. WINDMILL. ERIC C. RUT, Wrentham, N. D. Filed Jan. 20, 1902. Serial No. 59,332. (No model.)

Claim.—1. In a windmill, the combination of a rotary frame, a main vane carried by the rotary frame and capable of partial rotation to turn it from a vertical to a horizontal position, a pair of supplemental vanes arranged normally in an upright position and adapted to swing therefrom to approximately a horizontal position to form a vane at an angle to the main vane for turning the wind-wheel out of the wind, gear-meshing with each other and connected with the supplemental vanes, and connections between the supplemental vanes and the main vane, substantially as and for the purpose described.

2. In a windmill, the combination of a rotary frame, a wind-wheel shaft provided with a brake-wheel, a main vane having a horizontal shaft mounted on the frame and provided with a short arm, a supplemental vane arranged normally in an upright position and adapted to swing to an approximately horizontal position at an angle to the main vane, and connected with the said arm, whereby the main vane will be partially rotated when the supplemental vane is actuated, a brake-lever having a shoe arranged to engage the brake-wheel, and means for oscillating the brake-lever simultaneously with the supplemental vane, substantially as described.

3. In a windmill, the combination of a rotary frame, a wind-wheel shaft having a brake-wheel, a main vane journaled on the frame and capable of partial rotation, supplemental vanes, gears connected with the supplemental vanes and meshing with each other to cause the said supplemental vanes to oscillate in unison, means for connecting the supplemental vanes with the main vane, an arm connected with the supplemental vane, a bell-crank lever having diverging arms, one of the arms being

connected with the said arm, a brake-lever connected with the other diverging arm, and an operating-lever connected with the bell-crank lever, substantially as described.

4. In a windmill, the combination of a rotary frame, a main vane movably mounted on the frame to arrange it in an effective position and to carry it to an ineffective position, supplemental vanes mounted on the frame and normally extending upward and downward therefrom and capable of swinging simultaneously in opposite directions and adapted to be arranged approximately in a horizontal position to form a vane at an angle to the main vane, and means for connecting the main vane with the supplemental vanes, whereby the main vane will be arranged in an ineffective position when the supplemental vanes are in substantially a horizontal position, substantially as described.

698,117. PAPER BOX. ARTHUR C. JORDAN, Annapolis, Va. Filed Aug. 9, 1901. Serial No. 71,542. (No model.)

Claim.—The herein-described paper-box body having lips G struck and extending upwardly from its bottom at points adjacent to its ends, and also having its sides provided with projecting corner-flaps B to bear against the inner sides of its ends, and the said ends provided with reinforcement-flaps E of a die to fold inwardly on the inner sides of the ends and corner-flaps and extend to the bottom so as to entirely cover said ends and corner-flaps and secure the same in place, and further having the locking-flaps H arranged on and parallel to the bottom and divided by creases from the flaps E, and provided, in turn, with the transverse creases I resting in a dead-center, as and for the purpose set forth.

698,118. MANUFACTURE OF PAST-FIBER PULP. AUGUST KALHARR, Budapest, Austria-Hungary. Filed Aug. 17, 1901. Serial No. 73,572. (No specimens.)

Claim.—1. A process for the manufacture by mechanical agencies of past-fiber pulp for use in the production of paper, millboard and the like, consisting in washing and opening the raw material, in subjecting it to intermittent compressions removing it from the apparatus and allowing it to settle and in again subjecting it to intermittent compressions, substantially as described.

2. A process for the manufacture by mechanical agencies of past-fiber pulp, for use in the production of paper, millboard and the like, consisting in washing and opening the raw material, in subjecting it to intermittent compressions, removing it from the apparatus and allowing it to settle and in again subjecting it to intermittent compressions, under high air-pressure, substantially as described.

698,119. APPARATUS FOR TWISTING MAGADONOL. EDWARD E. KLEMMER, New York, N. Y., assignor to Frederick Danesi, Brooklyn, N. Y. Filed Apr. 2, 1901. Serial No. 54,107. (No model.)

Claim.—1. An apparatus for twisting material comprising a press provided with a plurality of apertures through which the dough may be forced, a vertical plunger for pressing the dough through the said apertures, rotary twisting devices mounted adjacent the said apertures and in communication therewith and opening laterally outwardly whereby in their rotary movement to impart a spiral or twisted form to the said material as it leaves the press.

2. An apparatus for twisting material comprising a press provided with a plurality of apertures through which the dough may be forced, a vertical plunger for pressing the dough through the said apertures, rotary twisting devices mounted adjacent the said apertures and in communication therewith and opening laterally outwardly whereby in their rotary movement to impart a spiral or twisted form to the said material as it leaves the press, and means connected with the said rotary twisting devices and with the operative mechanism of the press to impart motion simultaneously to the said vertical plunger and the said twisting devices.

3. An apparatus for twisting material, comprising a press provided with a plurality of apertures through which the dough is forced, devices mounted adjacent to said apertures for imparting a spiral or twisted form to the material as it passes therethrough, a conveyor mounted beneath the said twisting devices to receive the twisted material therefrom, and devices for imparting motion simultaneously to the operative mechanism of the press to the several twisting devices, and in the conveyor, whereby they operate in suitable relative speeds.

4. In an apparatus for twisting material, a twisting-die formed with a central bore adapted to receive the material therethrough, and opening laterally outwardly, the said die being adapted to rotate, whereby to impart a spiral or twisted form to the material.

5. In an apparatus for twisting material, a twisting-die formed with a central bore, adapted to receive the material therethrough, and opening laterally outwardly near the center of the die, and provided with a finger or projection at one side of said opening whereby to deflect the material as it leaves the die.

6. In an apparatus for twisting material, a twisting-die formed with a central bore adapted to receive the material therethrough and opening laterally outwardly, the said die being adapted to rotate, whereby to impart a spiral form to the material, and the lower end of the said die being adapted to the opening thereof being tapered or conical in form.

7. An apparatus for twisting material comprising a press provided with an aperture through which the dough is forced, a rotary twisting-die mounted in operative relation to the said aperture and formed with a central bore adapted to receive the material therethrough, and opening laterally outwardly and provided with a depending shaft beneath the said opening and being adapted to rotate whereby to impart a spiral or twisted form to the material.

8. An apparatus for twisting material, comprising a press formed with a central aperture therein, a gear-wheel mounted beneath the said aperture and revolvable around it, a twisting-die connected with the said gear-wheel and provided with a central bore communicating with the aperture of the press, and wider than the lower end thereof, and opening laterally of the said twisting-die, the said die being formed with a tapered or conical end beneath the said opening; and means for imparting motion to the said gear-wheel.

9. An apparatus for twisting material, comprising a press provided with a plurality of conical apertures through which the dough is forced, twisting devices mounted beneath the said apertures and provided with central bores wider than the lower ends of the said apertures and opening laterally of the twisting-die, and means for imparting to the material a spiral or twisted form as it leaves the said openings.

10. An apparatus for twisting material, comprising a press provided with a plurality of apertures through which the dough is forced, rotary twisting devices mounted beneath the said apertures and provided with central bores communicating with said apertures and opening laterally of the said die, gear-wheels connected with and surrounding said die and revolvable around the apertures, and a gear-wheel engaging and operating the gears of the said twisting devices.

11. An apparatus for twisting material, comprising a press provided with a plurality of apertures through which the dough is forced, rotary twisting devices mounted beneath the said apertures and formed with central bores communicating with said apertures and opening laterally of the said die, gear-wheels connected with and surrounding the twisting devices and revolvable around the apertures, a gear-wheel meshing with and operating the gears of the said twisting devices, a conveyor or apron beneath the said die, and means for simultaneously operating the last-named gear-wheel, the operative mechanism of the press, and the said apron.

12. An apparatus for twisting material, comprising a press provided with a plurality of apertures through which the dough is forced, rotary twisting devices mounted beneath the said apertures and formed with central bores communicating with said apertures and opening later-

ally of the said die, gear-wheels connected with and surrounding the twisting devices and revolvable around the apertures, a gear-wheel meshing with and operating the gears of the said twisting devices, a conveyor or apron supported beneath the twisting devices in an inclined position, descending in the direction of its movement, and means for imparting to the material a spiral or twisted form as it leaves the said openings.

13. An apparatus for twisting material, comprising a press provided with a plurality of apertures through which the dough is forced, rotary twisting devices mounted beneath the said apertures and formed with central bores communicating with said apertures and opening laterally of said die, gear-wheels connected with and surrounding the twisting devices and revolvable around the apertures, a gear-wheel meshing with and operating the gears of the said twisting devices, a conveyor or apron mounted beneath the said twisting device in an inclined position descending in the direction of its movement, trays detachably connected with the said apron, means upon the apron for catching the trays and carrying them in an inclined position beneath the twisting device, and means for simultaneously imparting motion to the gear-wheel which operates said twisting device, to the operative mechanism of the press, and to the said apron.

14. An apparatus for twisting material, comprising a press formed of a cylinder provided in its bottom with a plurality of conical apertures through which the dough is forced, and a screw-plunger, a shaft for operating the same, means connecting the said shaft and the screw-plunger whereby to operate the same, a vertical shaft connected with the said plunger-operating shaft and provided near its lower end with a spur-gear, a parallel vertical shaft geared in connection therewith and provided with a parallel spur-gear, a plurality of smaller gears revolvable mounted beneath the apertures of the press and provided with depending yokes, the said gear-wheels being geared together in connection with the spur-gears of the vertical shaft, a plurality of twisting-dies inserted into the said yokes and formed with central bores communicating with the said apertures and opening laterally outwardly near the center of the die and wider than the lower ends of the said apertures, the said twisting-dies being provided with tapered or conical ends, a conveyor or apron mounted beneath the said twisting-dies in an inclined position, descending in the direction of movement, trays detachably connected with the said apron, devices upon the said apron for catching the said trays and carrying them in an inclined position beneath the die, means for rotating the said apron, and means connected with one of the vertical shafts for operating the said rotating means.

15. In a material-press, the combination with a cylinder provided with a plurality of apertures therein and means for forcing the dough therethrough, of an inclined conveyor or apron mounted beneath the said cylinder and provided with means for rotating the same, trays detachably connected with the said apron and devices upon the said apron for catching the said trays and carrying them in an inclined position beneath the die.

16. In a material-press, the combination with a cylinder having an aperture therein and means for forcing the dough therethrough, of a rotary twisting-die mounted beneath the said aperture and communicating therewith, the upper portion of the said die which is in communication with the aperture being externally closed and provided with a central bore which extends partially through the said die and opens laterally at the bottom of said bore, the said die being provided with a depending shaft beneath the said aperture.

17. In a material-press, the combination with a cylinder having an aperture therein and means for forcing the dough therethrough, of a rotary twisting-die mounted beneath the said aperture and communicating therewith, the upper portion of the said die which is in communication with the aperture being externally closed and provided with a central bore which extends partially through the said die and opens laterally at the bottom of said bore, and a tapered or conical shaft or lower end depending from the die beneath the said opening.

18. In a material-press, the combination with a cylinder having an aperture therein and means for forcing the dough therethrough, of a rotary twisting-die mounted beneath the said aperture and communicating therewith, the upper portion of the said die which is in communication with the aperture being externally closed and provided with a central bore which extends partially through the said die and opens laterally at the bottom of said bore, and a tapered or conical shaft or lower end depending from the die beneath the said opening, and means for imparting rotary motion to the said die whereby when the dough is forced therethrough and outwardly through the lateral aperture it will be wound around the tapered or conical lower end and given a spiral form.

698,120. KITCHEN STOVE. EDWARD W. LEASE, Boston, Wm. Leach, assignor of leasehold to William A. Horton, Boston, Wm. Filed May 2, 1901. Serial No. 54,407. (No model.)

Claim.—1. A kitchen utensil consisting of a suitable handle and a curved spring-blade attached at one end to the handle with its back toward the handle, and having a spiral edge capable of yielding backward toward the handle gradually from its free toward its fixed end, substantially as described.

2. A kitchen utensil consisting of a suitable handle and a rotatable spiral spring-blade attached at one end to the handle with its back toward the handle, and having a spiral edge capable of yielding axially from its free end gradually toward its fixed end, substantially as described.

3. A kitchen utensil consisting of a suitable handle and a curved spring-blade adapted to be attached at one end to the handle and having a spiral edge capable of yielding backward toward the handle, said handle and blade having studs and openings which are arranged to be engaged with each other by the compression and expansion of the blade, substantially as described.

4. A kitchen utensil consisting of a rotatable spiral spring-blade and a handle having a flanged socket-plate in which the back of the blade is detachably fitted, the blade and handle being provided with interlocking studs and openings, substantially as described.

698,121. APPARATUS FOR HARDENING ROTARY CUTTERS. HENRY LINDSEY, Milner, England. Filed Jan. 14, 1902. Serial No. 90,306. (No model.)

Claim.—1. In apparatus for hardening rotary cutters, a vertically-mounted shaft, a vessel and two disks on the same, an annular space between the interior of the said vessel and the periphery of the said disks, and means for rotating the said shaft, the said disks being adapted to receive between them the cutter to be hardened and to rotate with the said shaft and vessel and the said space forming a passage for the hardening liquid, all combined substantially as and for the purpose set forth.

2. In an apparatus for hardening rotary cutters, a vertically-mounted shaft, a vessel and two cutter-holding disks on the same, a second vessel surrounding the first-named vessel, buckets in the bottom of the latter

and an annular space between the periphery of the said disks and the interior of the said first vessel and means for rotating the said shaft, the said second vessel holding the hardening liquid and the said buckets raising and circulating it from the latter through the said annular space against the teeth or cutting edges of the cutter to be hardened, all combined substantially as and for the purpose set forth.

3. In an apparatus for hardening rotary cutters, a vertically-mounted shaft, a vessel and two cutter-holding disks on the same, an annular space between the interior of the said vessel and the periphery of the said disks, a removable spindle in the said shaft carrying the cutter to be hardened and means for rotating the said shaft, the lower of the said disks supporting and the upper one resting upon the said cutter, all combined substantially as and for the purpose set forth.

698,122. COMBINED PENCIL-HOLDER AND SHARPENER. CLIFTON C. LOVISOY, Providence, R. I. Filed July 22, 1900. Serial No. 24,512. (No model.)

Claim.—1. In a device of the class described the combination with a tubular member adapted to receive a pencil in one end and a rubber eraser in the other, and having an opening formed in its side, of a pencil-sharpener secured in said tube opposite the opening therein, blocks fitted in the ends of the opening and engaging the end of the sharpener in hold the latter in place, and a rotatable cover having an opening corresponding in position and shape to the opening in the tube, said cover adapted when rotated to close the opening in the tube and conceal the sharpener.

2. As an improved article of manufacture the combination of a tubular member adapted to receive a pencil in one end and a rubber eraser in the other, said member having a longitudinal opening formed in its side and a raised band near one end, a file secured in the tube opposite the opening therein, blocks closing the end of the opening and engaging the end of the file to hold the latter in place and a rotatable cover mounted on the tube between the raised band and the eraser, to prevent its longitudinal movement, said cover having an opening corresponding to the opening in the tube to permit access to the file, substantially as specified.

698,123. WARP-STOP-MOTION DETECTOR. EDWARD MANNETT, Hopkinton, Mass., assignor to Draper Company, Hopkinton, Mass., a Corporation of Maine. Filed Dec. 2, 1901. Serial No. 25,122. (No model.)

Claim.—1. As a new article of manufacture, a detector-heddle for looms, made of an elongated, narrow strip of sheet metal having a longitudinal slot and a warp-receiving opening, and transverse, rounded wear members of greater thickness than the strip, secured in place at the top and bottom of the warp-receiving opening, to present convex bearing-surfaces for the warp and laterally extended beyond the flat faces of the heddle.

2. As a new article of manufacture, a warp-stop-motion detector made of an elongated, narrow strip of sheet metal having a substantially rectangular warp-receiving opening, and wear members substantially round in cross-section and having dotted ends, let into the said opening at the top and bottom thereof to present convex bearing-surfaces for the warp, the dotted ends embracing the sides of the opening.

3. As a new article of manufacture, a warp-stop-motion detector made of an elongated, narrow strip of sheet metal having a substantially rectangular warp-receiving opening, and means secured within said warp-

receiving opening to present convex bearing-surfaces for the warp, said means projecting beyond the flat faces of the detector, substantially as and for the purpose set forth.

698,124. CONTACT APPARATUS FOR ELECTRIC RAILWAYS. ALVAN MARBLE, Rochester, Pa. Filed Jan. 12, 1901. Serial No. 62,294. (No model.)

Claim.—1. In an electric-railway system, a contact device consisting of a contact-shoe, pivoted links at the respective ends of said shoe, and a flexible spring in the respective ends of which said links are pivoted, substantially as described.

2. A contact-shoe for electric railways, consisting of a contact-plate, a yielding spring, and links connecting the ends of the spring with the contact-plate, substantially as described.

698,125. TAKING-UP APPARATUS FOR KINETOGRAPHES. O. KAR HENRIKSEN, Berlin, Germany. Filed May 15, 1901. Serial No. 60,604. (No model.)

Claim.—1. In an apparatus of the character described, the combination with the supply and take-up rolls arranged side by side as described, of guides *a'*, arranged diagonally and a film adapted to travel from the supply-roll over the said guides the guide *a'* being so arranged that the film after passing over the same will be coincident with a vertical plane passing through the objective as set forth.

2. In an apparatus of the character described, the combination with the supply and take-up rolls arranged side by side, of guides *a'*, arranged diagonally, a film adapted to travel from the supply-roll over the said guides, the guide *a'* being so arranged that the film after passing over the same will be coincident with a vertical plane passing through the objective, and a casing surrounding the rolls and being provided with slots for the passage of the film.

3. In an apparatus of the character described, the combination with the supply and take-up rolls arranged side by side, of guides *a'* arranged diagonally, a guide-roller *c*, the drum *b* provided with pins, and a drum *d*, all adapted for cooperation as set forth.

698,126. GRINDING OR POLISHING MACHINES. JAMES H. HANCOCK, New York, N. Y., assignor to the White Outing Company, New York, N. Y., a Corporation of New Jersey. Filed June 1, 1901. Serial No. 62,297. (No model.)

Claim.—1. An apparatus for grinding or polishing articles, comprising a movable body, means for moving the body, and means for refrigerating the same, the refrigerant not being in direct contact with the exterior of the body, substantially as described.

2. An apparatus for grinding or polishing articles, comprising a movable body carrying an abrading-surface, means for giving motion to the body, and means for refrigerating the same, the refrigerant not being in direct contact with the exterior of the body, substantially as described.

3. An apparatus for grinding or polishing articles, means for preventing generation of heat therein consisting of a refrigerant in direct contact with the abrading-surface of the body, substantially as described.

4. An apparatus for grinding or polishing articles, comprising a movable body, and means for refrigerating the same internally, substantially as described.

5. An apparatus for grinding or polishing articles, comprising a movable body, and means for refrigerating the same internally and externally substantially as described.

698,127. WIRE-COUPLING. GEORGE L. MITCHELL, Cincinnati, Ohio, assignor of one-half to James H. Olson, Cincinnati, Ohio. Filed June 12, 1901. Serial No. 64,224. (No model.)

Claim.—1. A wire-coupling consisting of a sleeve having centrally-located holes at each end and each intended to receive a wire, a chamber at the inner end of each hole, the end wall of which forms a shoulder or abutment around each inner end, a plurality of locking-plates in each chamber and spacing-washers to separate them to permit each of the former to act independently, all being perforated and aligned to permit the projecting end of the inserted wire to enter and pass through them for engagement which latter is with the locking-plates only, the surface of the enlarged base of the washers being recessed to prevent any engagement thereof.

2. A wire-coupling consisting of a sleeve having centrally-located holes at each end and each intended to receive a wire, a chamber at the inner end of each hole, the end wall of which forms a shoulder or abutment around each inner end, a plurality of perforated locking-plates adapted to receive and hold the projecting end of the inserted wire, spacing-washers between these locking-plates to permit them to act each independently, they having also perforations, but of larger size than those in the locking-plates, the perforations in all these latter and in the washers being aligned to permit a wire end to enter, and a spring to hold them in proper position and alignment previous to the entrance of the wire.

698,128. DIFFERENTIAL AND REVERSING GEAR. JAMES H. MITCHELL, Philadelphia, Pa. Filed Oct. 22, 1900. Serial No. 22,515. (No model.)

Claim.—1. A device for transmitting rotary motion with varying speeds and directions having in combination two shafts, a series of power-transmitting devices arranged to couple said shafts and each coupling device to transmit its power at a different speed but in the same direction, means for connecting and disconnecting each of said devices, an additional power-transmitting device arranged to couple the shafts so as to rotate the driven shaft in the reverse direction to that in which it is driven by the series of shafts, a friction-brake, connected clutch and brake cones, as F F', and means for shifting said cones to connect the reversing device or apply the brake.

2. A device for transmitting rotary motion with varying speeds and directions having in combination two shafts, a series of frictional power-transmitting devices arranged to couple said shafts and each coupling device to transmit its power at a different speed but in the same direction, means for connecting and disconnecting each of said devices, an additional power-transmitting device arranged to couple the shafts so as to rotate the driven shaft in the reverse direction to that in which it is driven by the series of frictional power-transmitting devices, a friction-brake, connected clutch and brake cones, as F F', and means for shifting said cones to connect the reversing device or apply the brake.

3. A device for transmitting rotary motion with varying speeds and directions having in combination two shafts, a series of frictional power-transmitting devices arranged to couple said shafts and each coupling device to transmit its power at a different speed but in the same direction, means for connecting and disconnecting each of said devices, an additional power-transmitting device arranged to couple the shafts so as to rotate the driven shaft in the reverse direction to that in which it is driven by the series of frictional power-transmitting devices, a friction-brake, connected clutch and brake cones, as F F', and means for shifting said cones to connect the reversing device or apply the brake.

698,129. STORAGE-TANK. HENRY R. HINE, New York, N. Y., assignor to the American Sugar Refining Company, New York, N. Y., a Corporation of New Jersey. Filed Dec. 12, 1900. Serial No. 36,663. (No model.)

Claim.—1. A storage-tank, comprising a perforated casing, a perforated ventilating-pipe located within the tank, and a series of conical rings surrounding said pipe and superposed one upon the other.

2. A storage-tank, comprising a perforated casing, a perforated ventilating-pipe located within the tank, and a series of conical rings having radial wings projecting therefrom and surrounding said pipe and superposed one upon the other.

3. A storage-tank, comprising a perforated casing, a perforated ventilating-pipe within the tank, a series of ventilating-rings provided with wings superposed one upon the other and around said pipe and having said wings opened as regards each other and the interior of the tank.

4. A storage-tank, comprising a perforated casing, and a perforated ventilating-pipe formed of sections of decreasing diameter from the bottom upward and located within the tank.

5. A storage-tank, comprising a perforated casing, a perforated ventilating-pipe formed of sections of decreasing diameter from the bottom upward, and a series of ventilating-rings superposed one upon the other and surrounding said pipe.

6. A storage-tank, comprising a perforated casing, a top having a feed-opening, an inclined bottom having a delivery-pipe, and a perforated ventilating-pipe of decreasing diameter from the bottom upward within the tank.

698,180. SOFA-BEDSTEAD. ROBERT C. O'NEIL, New York, N. Y., assignor to Patrick R. Hickey, New York, N. Y. Filed Feb. 26, 1901. Serial No. 48,948. (No model.)

Claim.—1. In a sofa-bedstead, the combination, with a main frame embodying side bars and end uprights, and a pivoted extension attached thereto, of an approximately U-shaped support extending from said extension and embodying a horizontal part and extended arm, and a rail secured to each end upright and having respectively a stop for engaging the said support and a pawl for automatically throwing the support, substantially as shown and described.

2. In a sofa-bedstead, the combination, with a main frame embodying side bars and end uprights, and a pivoted extension attached thereto, of a U-shaped support pivoted to the said extension and having a longitudinal part, and a rail having a stop for engaging the support and a pawl for automatically throwing the support, and a wire rod and spring for maintaining frictional contact with the parts to keep them in position, and folding legs, substantially as shown and described.

3. In a sofa-bedstead, the combination, with a main frame embodying side bars and end uprights, and a pivoted extension attached thereto, of a U-shaped support pivoted to the said extension and having a longitudinal part, and a rail with a recess therein for engaging the support and a pawl for automatically throwing the support, and a wire rod and spring for maintaining frictional contact with the parts to keep them in position, and folding legs, substantially as shown and described.

698,181. MOTOR-VEHICLE. RALPH B. CLIM, Detroit, Mich. Filed Oct. 14, 1901. Serial No. 78,951. (No model.)

Claim.—1. In a motor-vehicle, the combination of a rigid motor-supporting frame, the motor-shaft journaled thereon, a bracket secured to the frame, a counter-shaft journaled therein and extending to the side of the frame, a crank for actuating said counter-shaft, and a gear connection from the counter-shaft comprising a clutch permitting the rotation of the motor-shaft independent of the counter-shaft or through the medium of said counter-shaft.

2. In a motor-vehicle, the combination with the body, of a supporting-frame therefor comprising side bars extending in adjacency to the sides of said body and secured thereto, cross-bars connecting said side bars and a motor extending longitudinally intermediate said side bars and rigidly connected to said cross-bars.

3. In a motor-vehicle, the combination with the body, of an angular supporting-frame therefor having parallel side bars extending in adjacency to and connected with the sides of said body, a motor-extending extending longitudinally across said frame and rigidly secured thereto, a motor-shaft extending transversely across said frame and a journal-bearing for said shaft secured to one of the side bars of said frame; the space between said bearing and casing being adapted to receive the fly-wheel and transmission-gearing.

4. In a motor-vehicle, the combination of a horizontally-arranged substantially rectangular frame, a motor-extending extending longitudinally across and rigidly secured in said frame, a frame extending upwardly from said horizontal frame, a motor-controlling shaft journaled therein, a body including said motor and frame and having its sides supported upon and in adjacency to the sides of said horizontal frame and an operating-

handle for said motor-controlling shaft extending without said body into proximity to the operator's seat.

5. In a motor-vehicle, the combination of a rigid motor-frame, the motor-shaft journaled thereon, a spring connection between the frame and motor, a drive-shaft from the motor-shaft in the drive-axis, a counter-shaft journaled on the motor-frame, and extending to the side thereof, an operating-crank for said shaft, and a drive connection between the counter-shaft and the motor-shaft permitting the rotation of the motor-shaft independently of the counter-shaft or through the medium of said counter-shaft.

6. In a motor-vehicle, the combination with a motor-frame, and its motor, of a yieldingly-supported body, a starting mechanism connected with the motor-shaft and comprising a counter-shaft extending to the side of the body, a bearing for the counter-shaft rigid on the motor-frame, and a crank on the counter-shaft at the side of the body.

7. In a motor-vehicle, the combination of a body, a rigid frame, the motor secured thereto, the motor-shaft, a starting-shaft journaled fixedly on said frame, a gear connection from the starting-shaft to the motor-shaft, and a permanently-attached crank for the starting-shaft projecting into proximity to the seat at the side of the body, and a clutch which permits the operation of the engine without turning the crank, but which permits the starting of the motor by rotating the crank.

8. In a motor-vehicle, the combination with a motor, a frame upon which said motor is rigidly mounted and a body yieldingly supported on said frame, of a flexible starting-shaft having one end journaled in said frame and connected with said motor, upon one side of the vehicle, the opposite end of said shaft extending to the opposite side of the vehicle and out through a bearing in the side of the body and a hand-crank upon the free end of said shaft.

9. In a motor-vehicle, the combination with the motor, a frame upon which said motor is rigidly mounted and a body yieldingly supported upon said frame, of a flexible starting-shaft having one end journaled in said frame and connected with said motor, upon one side of the vehicle, the opposite end of said shaft extending to the opposite side of the vehicle and out through a bearing in the side of the body and a hand-crank upon the free end of said shaft.

10. A motor-frame comprising a U-shaped horizontal frame formed of angle-bar, a bar connecting the free ends of said frame and having a depressed portion intermediate its ends with a motor-supporting middle thereon, a motor comprising an engine having its cylinder rigidly secured to said middle and a rigid crank-axle extending to the opposite side of the frame and rigidly secured thereto.

11. In a motor-vehicle, the combination of a frame supporting the motor, its shaft and a transmission-gearing, brackets on the frame and shafts journaled in said brackets, a drive connection from one of said shafts to the motor-shaft for starting the motor, said connection including a clutch, and a connection from the other shaft to the transmission-gearing.

698,182. TWO-SPEED DRIVING-GEAR FOR CYCLES. WILLIAM H. PALMER, Birmingham, England. Filed May 7, 1902. Serial No. 15,781. (No model.)

Claim.—1. In a two-speed driving-gear for cycles an inner drive K' placed inside the sliding toothed drive K to act as a buffer against the cross-bar I and a buffer-spring on placed thereon in combination with the hollow sliding drive K, the inner pinion D, the hub a, pinions B, sprocket-wheel A, hollow spindle H, operating-rod L and cross-bar I inside the spindle, the spring M in the spindle, the chain H attached to the rod L, the retaining-rod R with rounded edges on the end of the spindle to prevent of the free movement of the chain H substantially as described.

2. In a two-speed driving-gear for cycles, an inner drive K' placed inside the sliding toothed drive K to act as a buffer against the cross-bar I, a buffer-spring on placed thereon in combination with the hollow sliding drive K, the inner pinion D, the hub a, pinions B, sprocket-wheel A, hollow spindle H, operating-rod L, and cross-bar I inside the spindle, the spring M on the spindle, the chain H attached to the rod L, the flexible band F connected to the chain, the operating-lever O attached to the frame, the motor O' and the catch c to retain the lever in position substantially as described.

698,188. INCANDESCENT-LAMP SOCKET. WILLIAM E. FURBER, Watertown, Conn., assignor to the Watertown Mfg. Co., Watertown, Conn., a Corporation. Filed Apr. 9, 1901. Serial No. 65,989. (No model.)

Claim.—1. In a lamp-socket, the combination with a non-conducting plug formed with a chamber, of a spring located within and secured to the floor of the said chamber, a contact-plate secured to the plug at the open end thereof so as to close the said chamber, and formed with a central opening and a lateral opening and with key-bearings, a contact-bracket secured to the inside of the plug, entering the said opening and carrying a terminal screw, and also carrying a threaded stud which extends through the said central opening and provides for the attachment of a lamp a portion of which impinges against the outer face of the said plate; and a key having bearing in the bearings of said contact-plate.

2. In a lamp-socket, the combination with a non-conducting plug having a chamber, of a spring located within and secured to the floor of the chamber, a bracket secured to the outside of the plug, carrying a terminal screw and connected with the said spring, a contact-plate secured to the plug over the open end thereof and formed with a central opening and a lateral opening and with key-bearings, a contact-bracket secured to the outside of the plug and carrying the other terminal screw and also carrying a threaded stud which extends through the said central opening and provides for the application of the lamp which impinges against the outer surface of the said plate, and a key having bearing in the said plate and provided with a contact-piece which, when the key is properly turned, makes a connection between the said spring and the said contact-plate.

3. A key for incandescent-lamp sockets consisting of one or more pieces of non-conducting material and provided with a transversely-arranged contact-piece opposite points of which are brought into play for closing the circuit through the socket, the said contact-piece being entirely insulated from the body of the key.

4. A key for incandescent-lamp sockets, consisting of one or more pieces of non-conducting material, and provided with a transversely-arranged contact-pin the opposite ends of which are brought into play for closing a circuit through the socket when the key is turned a quarter-turn.

698,184. PROCESS OF DRYING REDWOOD LUMBER. EDWIN B. PERLHUIS, Berkeley, Cal. Filed July 17, 1901. Serial No. 63,066. (No specimens.)

Claim.—The process of drying redwood lumber by application under a mechanically-induced pressure of air and gases saturated with wa-

ter-vapor, followed by exhaustion of gases, air, vapor and up by a mechanically-induced vacuum and the subsequent filling of the vacuum in the wood with carbonic-acid gas, substantially as herein described.

698,185. BOTTLE. RICHARD W. FOLGER, New Haven, Conn. Filed Nov. 22, 1901. Serial No. 23,287. (No model.)

Claim.—A bottle formed with a neck-receiving pocket and an opening in said pocket through the side of the bottle, a coin in said pocket the edges of the pocket overlapping the edges of the coin, and an annular space around the pocket between it and the interior face of the bottle, substantially as described.

698,186. SERIES-MULTIPLE SWITCH. ALBERT A. FORTY, Evanston, Ill. Filed Feb. 24, 1902. Serial No. 99,108. (No model.)

Claim.—1. A series-multiple switch comprising a plurality of connections separately bridged between pairs of switch members, the corresponding members of the several pairs being arranged in sets, and a movable switch member for each set arranged to be connected with a circuit-terminal, said movable members constituting means for connecting up any desired number of said connections either in series or multiple as desired, substantially as described.

2. A series-multiple switch comprising a plurality of connections separately bridged between pairs of switch-fingers, the corresponding fingers of the several pairs being arranged in sets, contacts upon which the switch-fingers of one set normally rest, the contact for each finger being connected in a circuit to the switch-finger of the opposite set and next succeeding pair, and movable switch members for each set arranged for connection with the circuit-terminals and movable across the switch-fingers to make contact therewith and open the circuit-circuits, substantially as described.

3. A series-multiple switch comprising a plurality of separate connections, a corresponding number of fingers forming one set of switches, a corresponding number of fingers forming another set of switches, each connection being bridged across one pair of said fingers, a contact 'c' for each of the fingers of one set normally engaged thereby, means connecting the contacts 'c' with one of the fingers, a, and switch-bars E and F connected with the circuit-terminals and sliding across the respective sets of fingers to make successive contact with the several fingers thereof, the engagement of the bar F with each spring-finger d serving to separate the finger from its contact 'c', substantially as described.

698,187. BICYCLE HANDLE-BAR. JAMES T. FORTY, Detroit, Mich. Filed Mar. 10, 1901. Serial No. 61,328. (No model.)

Claim.—1. In combination with the head of a bicycle steering-post

provided with a cavity and with two journal-pins secured to the head and projecting through said cavity, a pair of handle-bars, each of which is provided on its inner end with arched racks, and with an annular row of teeth, a pair of plates adapted to engage over the journal-pins and one of which is provided with a double set of annular teeth adapted to engage with the notches between the teeth on the handle-bars, and means for securing the plates to the post-head with one of said plates engaging in the cavity, both of said plates being removable from the post-head, and reversible with respect to the post-head, substantially as described.

2. In combination with the head of a steering-post for bicycles, which is provided with a pair of journal-pins, handle-bars provided with arched racks, the handle-bars being adapted to engage over the journal-pins, and the arched racks being adapted to mesh together, a pair of plates adapted to engage over the journal-pins, said plates being removable and reversible with respect to the post-head, and arranged to engage on each side of the intermeshing ends of the handle-bars, a cam pressure-lever having fulcrum engagement with the journal-pins, and compressing engagement with one of said plates, substantially as described.

3. In combination with the head of a steering-post for bicycles which is provided with a pair of journal-pins, handle-bars provided with arched racks, the handle-bars being adapted to engage over the journal-pins and the arched racks adapted to mesh together, a pair of plates both of which are removable and reversible with respect to the post-head, and which are adapted to engage over the journal-pins arranged to engage on each side of the intermeshing ends of the handle-bars, a cam pressure-lever having a fulcrum engagement with the journal-pins and compressing engagement with one of said plates and an adjusting-screw arranged in the post-head to engage on the side of said plates opposite the cam, substantially as described.

4. In combination with the head of a steering-post for bicycles which is provided with a pair of journal-pins, handle-bars adapted to engage over the journal-pins provided with arched racks and with holding-teeth, a pair of plates removable from the post-head and reversible with respect thereto adapted to engage over the journal-pins and arranged to engage on each side of the ends of the handle-bars, one of said plates being provided with teeth adapted to engage in the notches between the teeth on the handle-bars, springs interposed between the plates, and means for forcing the plates into engagement with the handle-bars against the pressure of said springs, substantially as described.

5. In combination with a bicycle steering-post provided with a head and with journal-pins projecting therefrom, a reversible handle-bar connection therewith, comprising a pair of plates arranged to engage the handle-bar ends between them and to be themselves engaged and held with either plate contiguous to the post-head, one of said plates being provided with teeth adapted to engage in the notches between teeth on the handle-bars, substantially as described.

698,188. SCRAPER. ADOLF EMM, New York, N. Y., assignor to Dora Bitch, New York, N. Y. Filed June 20, 1901. Serial No. 99,211. (No model.)

Claim.—1. In a device of the nature indicated, a receptacle having walls, a handle integral with one of said walls, and a scraping member, substantially as described.

2. In a device of the nature indicated, a receptacle-wall having a reduced handle integral therewith and extending therefrom, a bottom having a cut-away portion fitting about said handle, and a scraping member, substantially as described.

3. In a device of the nature indicated, a receptacle having walls upon all sides and the top and bottom, the front wall being of less height than the distance between said top and bottom, whereby an opening is

left at the upper forward corner, and a scraping member projecting beyond said opening, substantially as described.

4. In a device of the nature indicated, a receptacle, a handle therefor, and a scraping member having lateral adjustment with relation to said handle, substantially as described.

5. In a device of the nature indicated, a receptacle having an opening leading thereto, the wall of said receptacle adjacent said opening having a slot therein, a scraping member fitting in said slot but of less width than said opening, whereby said scraping member can be adjusted laterally in said slot, and a handle upon said receptacle, substantially as described.

6. A scraping member for devices of the nature indicated, comprising an extension, means for attaching said extension to a receptacle, and a scraping-blade upon said extension and at an angle thereto, substantially as described.

7. A scraping member for devices of the nature indicated, comprising a body portion adapted to be secured to a receptacle, an angular extension upon said body portion, and a scraping-blade upon said extension and at an angle thereto, substantially as described.

698,189. MECHANISM FOR TRIMMING SLATS. JOSEPH EMMA, Jr., Hoboken, Ind., assignor to Harscoite Woodwork Company, Chicago, Ill., a Corporation. Filed July 20, 1901. Serial No. 79,679. (No model.)

Claim.—1. In a slat-trimming machine, the combination with the cutter-knife and with a support for the slat, of means for automatically delivering the slat in lateral direction into the path of the cutter-knife, and means for withdrawing the slat laterally from said knife.

2. In a slat-trimming machine, the combination with the cutter-knife and a support for the slat, of a pusher mechanism adapted to engage the edges of the slat and force them into the path of the cutter-knife and ejector mechanism adapted to discharge the slat laterally from the machine.

3. In a slat-trimming machine, the combination with the cutter-knife and a support for the slat, of a rack arranged in front of the knife for supporting a stack of slats, an opening at the bottom of said rack to permit the lowermost slat to be moved laterally into the path of the cutter-knife, pusher mechanism for advancing the slat laterally into the path of the cutter-knife and ejector mechanism for discharging the slat from the machine.

4. In a slat-trimming machine, the combination with the cutter-knife and with a suitable support for the slat, of pusher mechanism for advancing the slat laterally into the path of the knife and ejector mechanism

having points or hooks adapted to engage the bottoms of the slats and discharge them from the machine.

5. In a slat-trimming machine, the combination with the cutter-knife and with a suitable support for the slat, of pusher mechanism for advancing the slat laterally into the path of the knife, ejector mechanism for discharging the trimmed slat, and a spring for actuating the pusher mechanism in delivering the slat into the path of the knife.

6. In a slat-trimming machine, the combination with the cutter-knife and with a suitable support for the slat, of pusher mechanism for advancing the slat laterally into the path of the knife, a spring for moving said pusher mechanism to effect the delivery of the slat to the action of the knife, means for actuating said knife, ejector mechanism for discharging the trimmed slat and a lost-motion connection for actuating said ejector mechanism.

7. In a slat-trimming machine, the combination with the cutter-knife and with a suitable support for the slat, of pusher for advancing the slat laterally into the path of the knife, rock-arm for actuating said pusher, ejectors connected with said pusher for discharging the trimmed slat, spring mechanism for moving said pusher to cause the delivery of the slat to the path of the cutter-knife and means for moving said pusher and ejectors in opposite direction in order to withdraw the slat.

698,140. BOILER. JEAN A. REY and JEAN M. R. REY, Paris, France. Filed Nov. 6, 1901. Serial No. 81,314. (No model.)

Claim.—1. A steam generator or boiler, comprising a casing, a number of worms through which the liquid travels continuously, said worms arranged in a double series of tubular worms located above and below a central flat worm, the series above the central flat worm being concentrically arranged with respect to each other and the casing and the lower series being concentrically arranged with respect to each other and the casing and the double series being arranged so as to form a continuous flow for the passage of the hot gases entering the base of the casing, said flow continuing the gases alternately around surfaces of both series of concentric worms and of the central flat worm, in combination with a source of heat located below the lowermost worms.

2. A steam generator or boiler, comprising a casing, a flat worm located below the roof of the casing, a flat worm located above the base of the casing, a central flat worm located intermediate of the roof of the casing, a series of concentrically-arranged tubular worms located between the central flat worm and the roof of the casing, a similar series of tubular worms located below the central flat worm, all of said worms being detachably connected together to form a continuous passage for the water and steam, and all the worms arranged to form a continuous flow in the passage of hot gases entering the base of the casing, said flow conducting the gases to the interior and exterior surfaces of all the tubular worms and to the exposed surfaces of all the flat worms, in combination with a source of heat located directly below the lowermost tubular worm and an outlet located directly above the uppermost tubular worm.

3. A steam generator or boiler, comprising a casing, a flat worm located centrally within the casing, a series of tubular worms arranged concentrically with the wall of the casing and with each other located above the central flat worm, a second series of similarly-arranged tubular worms located below the central flat worm and having their pipes larger in diameter than the pipes of the upper series, a water-inlet pipe discharging into the upper series of tubular worms, a steam-outlet pipe leading from the lower series of tubular worms and traversing the central flat worm, and the innermost tubular worm of the upper series, detachable couplings connecting all the worms together to form a continuous passage for the water

and steam through the worms, in combination with a source of heat located below the lower series of tubular worms and an effluvia located above the upper series of worms, the worms being arranged to form a continuous passage for the gas from the burner around all the worms and into the effluvia.

4. A steam generator or boiler, comprising a casing, a double series of tubular and concentric worms arranged within the casing, a central flat worm above which a series of tubular worms is arranged and below which the other series of worms is located, the pipes of the worms above the central flat worm being of smaller diameter than the other worms, a source of heat located below the lower worms and a water-inlet pipe leading to the upper worms, said worms arranged so that the heat first traverses the space between the lower tubular worms and under the flat worm and then traverses the space between the upper tubular worms and over the flat worm, and a series of couplings connecting the various worms together to form a continuous passage for the water and steam through the worms.

698,141. CALCULATOR. GEORGE ROBERT, Passaic, N. J., assignor to the Carlin Manufacturing Company, Carlin, N. J., a Corporation of New Jersey. Filed Aug. 8, 1901. Serial No. 71,297. (No model.)

Claim.—1. In an instrument of the character set forth, the combination of a fixed casing, a drum revolvable within the same, and a cylindrical shutter revolvably interposed between the two and having spirally-arranged slots, and connections from said drum and shutter respectively to the exterior of said casing whereby said drum and shutter may be revolved independently of and relatively to each other in either direction, as set forth.

2. In an instrument of the character described, the combination of a cylindrical drum, a casing having an opening through which portions of said drum may be exposed, and a cylindrical shutter inclosing said drum and inclosed with the latter in said casing, the said shutter having a series of slots arranged to register but one at a time with said opening and expose the desired portion of the drum and conceal the remainder and an additional practically continuous slot, and means for rotating said drum and shutter within the casing, substantially as described.

3. In an instrument of the character set forth, the combination of a drum, a casing having a continuous longitudinal opening through which a portion of said drum may be exposed, and a shutter mounted to revolve in said casing and over said drum and having openings adapted to register but one at a time with said opening in the casing to expose the coincident portion of the drum and having provision for practically continuous exposure of a circumferential portion of the drum, substantially as described.

4. In an instrument of the character set forth, the combination of a cylindrical drum, a casing having an opening through which a portion of said drum may be exposed, a cylindrical shutter inclosing said drum and inclosed with the latter in said casing, means for rotating said drum and shutter independently within said casing, the said shutter having a series of slots adapted to register but one at a time with said opening and expose the desired portion of the drum and conceal the remainder, and an additional practically continuous slot, and means for holding said shutter against rotation when desired, substantially as described.

5. In an instrument of the character set forth, the combination of a cylindrical drum, a casing having an opening through which the desired portion of said drum may be exposed, a cylindrical shutter inclosing said drum and inclosed with the latter in said casing, said shutter having a series of slots adapted to register but one at a time with said opening and expose the desired portion of the drum and an additional practically continuous slot for exposing another portion of the drum, means for rotating said drum and shutter independently, means for holding said shutter against rotation when desired, and means for limiting such rotation in either direction, as set forth.

6. In an instrument of the character set forth, a casing having a longitudinally-extending opening and a cylindrical drum, in combination with a cylindrical shutter inclosing said drum and inclosed with the latter in said casing, the said shutter having a slot matching to a circumferential portion of said drum and a series of spirally-arranged slots but one

slot coinciding with the longitudinal opening at a time and each matching to the desired portion of the drum, the said slots adapted to register with said opening and allow an element of computation on said drum and the result of the desired computation to be read adjacent to the element of computation on said casing, all substantially as herein specified.

7. In an instrument of the character set forth, a casing, a drum inclosed therein, a series of circumferential ridges on said drum, and a series of relatively independent figure-bearing strips secured in the grooves between said ridges and protected by the latter, marks on said ridges and corresponding marks on said strips to aid in properly locating said strips on said drum, and means for rotating said drum within said casing and exposing said figures to sight in an opening therein, all combined substantially as herein specified.

8. The casing A having the opening a and end plates A' A', shutter C having heads C' C' and tubular extensions C'' passing through said end plates, and the circumferential slot c' and spirally-arranged slots c, the shaft B passing through said extensions, the drum D on said shaft and inclosed in said shutter, and means for rotating the latter and said drum, all combined substantially as herein specified.

9. The combination of casing A having the opening a and end plates A' A', shutter C and its heads C' C' inclosed in said casing, said shutter having the circumferential slot c' and slots c, the latter being spirally arranged so that only one of the same will be exposed at a time through the casing-opening, the others being masked by said casing, drum D inclosed within said shutter, and means for rotating said drum and shutter independently, one of said shutter-heads having a series of recesses, and means on the adjacent end plate to engage frictionally with said recesses, substantially as specified.

10. The casing A having the opening a and end plates A' A', shutter C having the circumferential slot c' and spirally-arranged slots c and heads C' C' inclosed in said casing, drum D inclosed in said shutter, and means for rotating said drum and shutter independently, in combination with a series of recesses c' in one of said heads, a spring D on the adjacent end plate carrying a pin D' extending through said end plate and adapted to engage frictionally with said recesses, and means as the lever D' and wedge-block D'' thereon for withdrawing said pin when desired, all substantially as herein specified.

11. The casing A having the opening a and end plates A' A', shutter C having the circumferential slot c' and spirally-arranged slots c and heads C' C' inclosed in said casing, drum D inclosed in said shutter, and means for rotating said drum and shutter independently, in combination with a flange C' on one of said heads, and a stop A' set in the adjacent end plate and carrying with said flange to limit the movement of said shutter, all substantially as herein specified.

698,142. BUTTERHOLE-CUTTER. GEORGE W. L. ROBERT, Seattle, Wash., assignor by direct and mesne assignments to Stephen H. Long, Seattle, Wash. Filed June 12, 1901. Serial No. 64,269. (No model.)

Claim.—1. In a butterhole-cutter, the combination with the pivotally-connected handles and the jaws, of a blade having a straight cutting edge and a cutting edge with a straight portion terminating in an eye and disposed oppositely to each other, means to secure said blade to one of the said jaws so that either of the said cutting edges may be moved into and retained in operative position, and a dis-closure having a plurality of faces rotatably mounted permanently upon the other jaw, means to lock the said dis-closure to any one position, and the clasp-gaging means.

2. In a butterhole-cutter, the combination with the pivotally-connected handles and jaws, of a blade having a straight cutting edge and a cutting edge with a straight portion terminating in an eye and disposed oppositely to each other, means to secure said blade to one of the said jaws so that either of the said cutting edges may be moved into and retained in operative position, and a dis-closure having a plurality of faces rotatably mounted permanently upon the other jaw.

698,143. RAILWAY ELECTRIC SIGNAL AND SAFETY APPARATUS. WILLIAM E. RAYMOND, Denver, Colo., assignor of one-half to Abraham V. Tiller, Omaha, Colo. Filed Oct. 12, 1900. Serial No. 32,880. (No model.)

Claim.—1. The combination with air-brake mechanism, a throttle-valve on the engine, and a hand-lever for controlling said valve, the said lever being normally locked when the throttle-valve is open, of a

cylinder mounted on the engine, a piston located therein, a connection between said piston and the hand-lever for unlatching the lever and actuating the same to close the throttle-valve when the piston is actuated, an electromagnet mounted on the engine, a conduit connecting the train-brake pipe with the cylinder, a normally closed valve located in said conduit, a connection between said valve and the magnet whereby the valve is opened as the magnet is energized, allowing the air to pass to the cylinder and actuate the piston, whereby the lever is unlatched and operated to close the throttle-valve, the cylinder being provided with a port so located as to allow the air to escape after actuating the piston, whereby the necessary reduction is effected for setting the brakes.

2. The combination with a source of electricity carried by the train, of an electromagnet located on the engine and connected with said source, means located on the road-bed and connected with the magnet for energizing the same when trains have approached within a predetermined distance, a hand-lever for closing the throttle-valve on the engine, said lever having a removable device normally locking the lever in the adjusted position when the throttle-valve is open, a cylinder located on the engine, a piston in the cylinder, a rod connected with the piston, arranged to engage the hand-lever locking device, and furnished to unlock the same when the piston is actuated, a conduit leading from a source of compressed air, to the cylinder, a normally closed valve located in said conduit, a connection between the valve and the electromagnet whereby as the latter is energized the valve is opened allowing the air to pass to the cylinder whereby the piston is actuated and the hand-lever operated to close the throttle-valve.

3. The combination with air-brake mechanism, of an electromagnet carried by the train, and provided with a movable core surrounded by the magnet-wire, a normally closed valve connected with the train-brake pipe and provided with a protruding stem, a port connected with the core of the magnet and provided with an offset arranged to engage the valve-stem and depress the latter to open the valve when the magnet is energized, a source of electricity carried by the train and with which the magnet is connected, and means located on the road-bed and connected with the electric source, for closing the circuit when the trains have approached within a predetermined distance, whereby the magnet is energized, the valve opened and the air allowed to escape, causing the necessary reduction of pressure to apply the brakes.

4. The combination with an electric source carried by the train, and means located on the road-bed and connected with said source for closing the circuit when two trains have approached within predetermined limits, and air-brake mechanism, of a hand-lever provided with a movable dog normally locking the lever when the throttle-valve is open, a cylinder, a piston located therein, a rod connected with the piston and provided with an offset arranged to raise and unlatch the dog when the piston is actuated, and then actuate the lever to close the throttle-valve, a conduit leading from the train-brake pipe to the cylinder, a normally closed valve located in said conduit, and provided with a protruding stem, an electromagnet provided with a movable core, a rod connected with said core and provided with an offset and a reduced portion, a spring normally holding

the reduced portion of the rod in a position engaging the valve-stem, whereby the valve remains closed, the arrangement being such that when the magnet is energized, the rod is actuated to bring its offset in contact with the stem whereby the latter is depressed and the valve opened, allowing the air to pass to the cylinder and actuate the piston, and unlatch and operate the hand-lever, the cylinder being provided with a port allowing the air to escape after the piston has been actuated, whereby the necessary reduction of pressure is effected to apply the brakes.

698,144. SOAP-GRANULATOR. JOHN BURROWS, Philadelphia, Pa., assignor, by mesne assignments, to Ralph W. Cunningham, New York, N. Y. Filed May 4, 1901. Serial No. 52,572. (No model.)

Claim.—1. In a soap-granulator, a horizontally-disposed cylindrical-shaped body portion and support for the same, a revolvable cylindrical-shaped granulating member within the body portion having at its periphery knives extending longitudinally of the member and provided with outwardly-extending teeth at the periphery of the member, caps applied to the ends of the body portion and having a part thereof curving as end abutments to retain the granulating member in position, and a tube opening into the body portion and adapted to contain soap to be granulated by contact with said knives, substantially as described.

2. In a soap-granulator, a body portion and a support for the same, a revolvable granulating member consisting of knives extending longitudinally of the axis of the member and provided with outwardly-extending teeth, the teeth of one blade inclining in the opposite direction to the teeth of another blade, and a tube opening into the body portion and adapted to contain soap to be granulated by contact with the teeth of the knives, substantially as described.

3. In a soap-granulator, a body portion, a revolvable granulating member consisting of knives extending longitudinally of the axis of the member and set at an angle to its axis, and means for receiving soap to be granulated by the knives, substantially as described.

4. In a soap-granulator, a body portion, a revolvable granulating member consisting of knives extending longitudinally of the axis of the member and provided with outwardly-extending teeth, the teeth of one knife being staggered in relation to the teeth of another knife, and means for receiving soap to be granulated by the teeth of the knives, substantially as described.

5. In a soap-granulator, a body portion, a revolvable granulating member consisting of toothed knives extending longitudinally of the axis of the member and set at an angle to its axis, the teeth of one knife being staggered in relation to the teeth of another knife, and means for receiving soap to be granulated by the toothed knives, substantially as described.

6. In a soap-granulator, a body portion and support for the same, a shaft provided with plates revolvably supported in said body portion, toothed blades extending from one plate to the other and supported by the plates, said blades being arranged at an angle to the axis of said shaft and the teeth of one blade being staggered in relation to the teeth of another blade, a tube adapted to receive soap to be granulated by the toothed blades.

and a follower in the tube to press the soap against the blades, substantially as described.

7. In a soap-granulator, a tube adapted to receive the soap to be granulated, knives for granulating the soap, and a rod passing centrally through the tube and adapted to serve as a guide for the soap, substantially as described.

8. In a soap-granulator, a tube adapted to receive the soap to be granulated, knives for granulating the soap, a constantly-apertured weight in the tube, and a rod passing centrally through the tube and weight and having a head adapted to serve as a guide for the soap and to prevent the weight from passing from off the lower end of the rod, substantially as described.

698,145. SMOKE-ABATING DEVICE. FRED E. SELLMAN, JR.
Loda, Mo. Filed Aug. 17, 1901. Serial No. 72,386. (No model.)

Claim.—1. The combination with an air-inlet leading to a distributing-chamber, of passages connecting said distributing-chamber with chambers behind the bridge-wall, perforated tiles forming the roof of said last-mentioned chambers, tube-tiles supported by said roof, the bases of said tube-tiles registering with the perforations in the roof, lateral openings in the tube-tiles, and closures for the upper ends of said tube-tiles, substantially as described.

2. The combination with a distributing-chamber opening to atmosphere, of passages leading from said distributing-chamber into a plurality of chambers located immediately behind the bridge-wall, said plurality of chambers having gradually-restricted inlet-openings, hollow tube-tiles arranged in rows above said chambers, the tubes of one row being staggered with respect to those of the next adjacent row, all of said tubes being provided with lateral openings, and closures for the upper ends of the tubes, substantially as described.

3. The combination with an air-inlet, of a heating-chamber connected therewith and having discharge-openings in its upper portion, said heating-chamber being arranged under the draft-flue and rearwardly of the bridge-wall, rows of tubes connected with the discharge-openings in said chamber and traversing the smoke-flue, said tubes having lateral openings for the discharge of heated air, and tiles provided with caps for receiving and closing the upper ends of said tubes, substantially as described.

698,146. GATE FOR BROTHERS OR CHUTME. AUGUSTUS SMITH,
New York, N. Y. Filed Jan. 31, 1902. Serial No. 99,616. (No model.)

Claim.—1. The combination of the discharge-spout of a hopper or chute with two pivoted gate-valves, having their adjacent edges spaced apart but overlapping when the valves are closed, as and for the purpose described.

2. The combination of the discharge-spout of a hopper or chute with two gate-valves pivoted one below and the other above its gate-flap, the adjacent edges of the gates being spaced apart when the valves are closed, as and for the purpose described.

3. The combination of the discharge-spout of a hopper or chute with two pivoted valves, having curved gates to lie across the spout with their edges overlapping, but spaced apart when the valves are closed, substantially as described.

4. The combination of the discharge-spout of a hopper or chute with two valves consisting of gates and side arms, by which they are pivoted, said gates being adapted when closed to lie across the spout with their edges overlapping but spaced apart, and by their joint action close the spout, substantially as described.

5. The combination of the discharge-spout of a hopper or chute with two gate-valves, one pivoted above and the other pivoted below its gate-flap, the latter of the two valves being pivoted to stay in either its open or closed position by gravity.

6. The combination of the discharge-spout of a hopper or chute with two gate-valves, one pivoted below and the other pivoted above its gate-flap, and means for locking the latter of the two valves in its open or closed position.

7. The combination of the discharge-spout of a hopper or chute with two valves, consisting of gates and side arms by which they are pivoted, said gates being adapted, when closed, to lie across the spout with their adjacent edges spaced apart, but by their joint action closing the spout, substantially as described.

698,147. PICK. EDWARD A. SMITH, Fowler, Colo., assignor to F. W. Nash and R. H. Sprague, Denver, Colo. Filed Aug. 14, 1906. Serial No. 77,098. (No model.)

Claim.—1. The combination with a pick-eye having a polygonal opening and transverse ribs on the interior and walls of said opening, of pick-points having shanks polygonal in cross-section adapted to said opening and formed with grooves to engage said ribs, and a wedge driven into said opening between said shanks and spreading them apart and holding the grooves of the shanks locked to the ribs of the opening, substantially as set forth.

2. The combination of a pick-eye having an opening polygonal in cross-section, pick-points having shanks polygonal in cross-section adapted to enter said opening, the pick-point shanks and the adjacent wall of the eye being respectively provided with corresponding locking recesses and projections, and a wedge-shaped locking-key inserted in said opening between said shanks.

698,148. BOTTOM FOR HEAT-HEATING FURNACE. FREDERICK P. BERRY, Pittsburgh, Pa. Filed Jan. 26, 1906. Serial No. 84,548. (No model.)

Claim.—A bottom for heat-heating furnace formed of a loose mass of hard-burned non-combustible balls or approximately spherical bodies, providing interstitial passages and a support for the plates upon the higher portions of the balls, substantially as set forth.

698,148.

698,149. CUFF-HOLDER. ELMER GUNDEKER, Brooklyn, N. Y.
Filed June 23, 1901. Serial No. 66,573. (No model.)

Claim.—1. The combination is a cuff-holder, of a rod provided with a device for fastening into a cuff-buttonhole, and a clamp attached to said rod and consisting of a base-plate provided with a head and an arched spring-plate pivoted on said rod and adapted to snap over said head substantially as described.

2. The combination is a cuff-holder, of a base-plate A, a head a thereon, an arched clamp B pivoted on said plate A, a curved end d thereof adapted to snap over said head a, a rod d fixed in said plate A and constituting the pivot of said clamp B, and a device on the end of said rod d adapted to be secured in a buttonhole of the cuff, substantially as described.

698,150. PROCESS OF PURIFYING SUGAR AND SOLUTIONS THEREOF. CLARENCE A. SCHWENK and CHARLES A. KENN, New York, N. Y., assignors to Federal Refining Company, Jersey City, N. J., a Corporation of New Jersey. Filed Nov. 14, 1901. Serial No. 82,196. (No specimens.)

Claim.—1. In the method of cleaning sugar from its impurities, the step which consists in mixing with the impure sugar a sulfonated fluid cleaning agent, substantially as described.

2. In the method of cleaning sugar from its impurities, the step which consists in mixing with the impure sugar a sulfonated body, substantially as described.

3. In the method of cleaning sugar from its impurities, the step which consists in mixing with the impure sugar a sulfonated acid body, substantially as described.

4. In the method of cleaning sugar from its impurities, the step which consists in mixing with the impure sugar a sulfonated derivative of a resinous body, substantially as described.

5. The method of cleaning sugar from its impurities, consisting in mixing with the impure sugar a sulfonated body, substantially as described, and then separating the sulfonated body and impurities carried by it, from the sugar, substantially as described.

698,151. TYPE-WRITING MACHINE. BERNARD C. BERNETT,
Humboldt, N. J., assignor to Jacob Faber, New York, N. Y. Filed Sept. 26, 1906. Serial No. 731,941. (No model.)

Claim.—1. In a type-writing machine, the combination of a line-space wheel, a check therefor, a cylindrical platen rotatable independently of the line-space wheel, a brake constructed to prevent backlash between the platen and the line-space wheel, a main paper-feed roller bearing against the platen, and a thumb-wheel, as 30, provided with means for turning both the platen and the said main feed-roller independently of the line-space wheel, without releasing said brake against the opposition thereof, the rotation of the platen being in the same direction as the rotation of said thumb-wheel.

2. In a type-writing machine, the combination of a line-space rubber-wheel, a spring-check constructed to ride over the teeth thereof, a cylindrical platen rotatable independently of the line-space wheel, a master-brake arranged between the line-space wheel and the platen, whereby either the line-space wheel may be actuated by the platen or the platen may be actuated by the line-space wheel, and a thumb-wheel, as 30, provided with means for turning the platen relatively to the line-space wheel, without releasing said master-brake and against the opposition thereof, and without turning the line-space wheel.

3. In a type-writing machine, the combination of a line-space wheel, a check therefor, a cylindrical platen rotatable independently of the line-space wheel, a brake constructed to prevent backlash between the platen and the line-space wheel, and a thumb-wheel, as 30, arranged concentrically with the platen and provided with means for turning the platen relatively to the line-space wheel without releasing said brake and against the opposition thereof, said thumb-wheel 30 being constructed to turn during each operation in the same direction as the platen, but at greater speed.

4. In a type-writing machine, the combination of a platen-frame, a shaft mounted therein, a cylindrical platen and a line-space wheel mounted upon said shaft, a thumb-wheel, as 34, fixed upon the shaft, said platen being rotatable independently of the line-space wheel, a brake constructed to prevent backlash between the platen and the line-space wheel, and a thumb-wheel, as 30, also mounted upon the shaft and rotatable relatively to the platen and provided with means for turning the platen relatively to the line-space wheel without releasing said brake and against the opposition thereof, the rotation of the platen being in the same direction as the rotation of said thumb-wheel.

5. In a type-writing machine, the combination of a line-space wheel, a cylindrical platen, a shaft therefor, an axially-arranged platen-cleave mounted to rotate upon the shaft, means for connecting the line-space wheel to the shaft, a planet-wheel arranged upon said cleave, a wheel fixed upon said shaft and meshing with said planet-wheel, and a manually-operated wheel engaging said planet-wheel.

6. In a type-writing machine, the combination of a line-space wheel, a cylindrical platen, a shaft therefor, an axially-arranged platen-cleave mounted to rotate upon the shaft, means for connecting the line-space wheel to the shaft, a planet-wheel arranged upon said cleave, a wheel secured upon said shaft and meshing with said planet-wheel, a manually-operated wheel engaging said planet-wheel, and a brake for opposing the rotation of said cleave upon said shaft.

7. In a type-writing machine, the combination of a line-space wheel, a check therefor, a cylindrical platen, an intermediate-arranged differential gearing for turning the platen with reference to the line-space wheel, a brake constructed to prevent backlash between the platen and the line-space wheel, and a thumb-wheel, as 30, operatively connected to said differential gearing.

8. In a type-writing machine, the combination of a line-space wheel, a check therefor, a cylindrical platen, a train of three wheels operatively connected to the line-space wheel and the platen and constructed to vary the relative circumferential positions of the line-space wheel and the platen, a brake constructed to prevent backlash between the platen and the line-space wheel, and a thumb-wheel, as 30, for operating said train without releasing said brake and against the opposition thereof.

9. In a type-writing machine, the combination of a line-space wheel, a cylindrical platen, a train of three wheels for rotating the platen without moving the line-space wheel, and a thumb-wheel, as 30, for operating said train.

10. In a type-writing machine, the combination of a line-space wheel, a check-spring therefor, a cylindrical platen, a train of three wheels arranged intermediate the line-space wheel and the platen, one wheel of said train of three wheels being a planet-wheel and meshing with both of the other wheels in said train, and a thumb-wheel, as 30, for operating said train, the construction and arrangement being such that during the operation of thumb-wheel 30, the line-space wheel remains stationary.

11. In a type-writing machine, the combination of a cylindrical platen connected with a wheel, as 24, a line-space wheel connected with a wheel, as 26, which engages said platen-wheel, and a manually-operated wheel, as 22, which also engages said platen-wheel.

12. In a type-writing machine, the combination of a platen, a gear-wheel as 24 connected thereto, a line-space wheel, a gear-wheel as 25 connected to said line-space wheel and in mesh with said wheel 24, and a manually-actuated wheel as 23 also in mesh with said wheel 24.

13. In a type-writing machine, the combination of a cylindrical platen, a line-space wheel, a check therefor, a planet-wheel, as 24, means for connecting said planet-wheel to the platen, a wheel, as 26, connecting said planet-wheel to the line-space wheel, a brake constructed to prevent backlash between the platen and the line-space wheel, and a thumb-wheel, as 30, constructed to cause a movement of the planet-wheel relatively to the line-space wheel without releasing said brake and against the opposition thereof.

tion thereof, so as to vary the relative circumferential positions of the platen and line-space wheel.

14. In a type-writing machine, the combination of a cylindrical platen connected with a planet-wheel, as 24, a line-space wheel connected with a wheel, as 25, of larger diameter than the planet-wheel and in engagement therewith, and a manually-operated centrally-arranged wheel, as 23, engaging the planet-wheel and constructed to rotate the latter and cause it to swing around the platen-axis in consequence of its said engagement with the wheel 25.

15. In a type-writing machine, as a means for adjusting the paper, the combination of a cylindrical platen, a concentric line-space wheel, and a train of three gear-wheels having axes parallel with the platen-axis and constructed to rotate the platen relatively to the line-space wheel.

16. In a type-writing machine, as a means for adjusting the paper, the combination of a cylindrical platen, a concentric line-space wheel, a train of three gear-wheels having axes parallel with the platen-axis and constructed to turn the platen relatively to the line-space wheel, and a thumb-wheel secured to one of said gear-wheels.

17. In a type-writing machine, as a means for adjusting the paper, the combination of a cylindrical platen, a concentric line-space wheel, a train of gear-wheels having axes parallel with the platen-axis and constructed to turn the platen relatively to the line-space wheel, and a thumb-wheel secured to one of said gear-wheels, the rotation of the platen being in the same direction as the rotation of said thumb-wheel.

18. In a type-writing machine, as a means for adjusting the paper, while the line-space wheel is stationary, the combination of a cylindrical platen connected with a toothed wheel, a line-space wheel connected with a toothed wheel, a third toothed wheel constructed to cause a movement of the platen toothed wheel relatively to the line-space toothed wheel, and a thumb-wheel for actuating the said third toothed wheel, the rotation of the platen being in the same direction as the rotation of said thumb-wheel.

19. In a type-writing machine, the combination of a line-space wheel connected with a toothed wheel, a cylindrical platen connected with a planet-wheel in mesh with said toothed wheel, a centrally-arranged pinion arranged in mesh with said planet-wheel, and a thumb-wheel for operating the said centrally-arranged pinion.

20. In a type-writing machine, the combination of a line-space wheel connected with a crown gear-wheel, a cylindrical platen connected with a planet-wheel arranged within said crown-wheel and in mesh with the teeth thereof, a centrally-arranged pinion in mesh with the teeth of the planet-wheel, and a thumb-wheel for operating the pinion.

21. In a type-writing machine, the combination with a cylindrical platen, of a concentric actuator 14, a planet-wheel 24 secured thereto, a crown-wheel 25 including said planet-wheel and in mesh therewith and rotatably connected to a line-space wheel, and a drum 30 including the crown-wheel and provided with a central pinion 23 in mesh with the planet-wheel 24.

22. The combination of two concentrically-arranged toothed wheels of substantially equal diameter, one wheel having more teeth than the other and the teeth in each wheel being evenly spaced, and a pinion constructed to be rotated by one of the wheels and also arranged in mesh with the other wheel, so that upon the rotation of either of said concentric wheels the other thereof is caused to rotate at a different angular speed.

23. The combination of two concentrically-arranged wheels, a relatively fixed pinion in engagement with both wheels and constructed to be rotated by one thereof, and to cause the other thereof to rotate at a different angular speed, and means called into action at the relative rotation of said concentrically-arranged wheels for causing them to have a relative lateral movement.

24. In a type-writing machine, the combination of a platen-frame, a line-space wheel, a platen mounted concentrically with said line-space wheel, and a rotary device mounted upon the platen-frame and connected to the line-space wheel and to the platen, and constructed to produce automatically a variation in the relative circumferential positions of the platen and the line-space wheel.

25. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel mounted concentrically with said platen, and a train of wheels constructed to vary the relative circumferential positions of the line-space wheel and the platen, all of said platen, line-space wheel and train of wheels having parallel axes.

26. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel mounted concentrically with said platen, and a train of three wheels, one of said three wheels being mounted upon the platen-frame, constructed to vary the relative circumferential positions of the line-space wheel and the platen.

27. In a type-writing machine, the combination of a platen-frame, a platen, a line-space wheel, and a wheel operated by and arranged concentrically of the line-space wheel and operatively connected to the platen,

and constructed to cause the platen to turn through aliquot parts of a revolution at corresponding movements of the line-space wheel through aliquot parts of a revolution.

28. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel, a wheel operatively connected to the platen, all of said wheels and the platen being concentrically arranged, and a pinion as 52, mounted upon a relatively fixed axis and connecting the wheels so as to cause the platen-wheel and the platen to rotate at different speeds from the line-space wheel.

29. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel, a toothed wheel secured thereto, a companion toothed wheel concentric therewith, and means for connecting the said toothed wheels in a manner to cause the platen to rotate at a speed unequal to that of the line-space wheel.

30. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel, a toothed wheel operatively secured to the platen, a companion toothed wheel secured to the line-space wheel, all of said wheels being concentric with the platen and the said toothed wheels being of substantially equal diameter and provided with unequal numbers of teeth, and a pinion mounted upon a relatively fixed axis and arranged in mesh with both said companion wheels, whereby the platen is caused to rotate at a speed unequal to that of the line-space wheel.

31. In a type-writing machine, the combination of a line-space wheel, a platen, a wheel, as 47, operatively connected to the platen, a pinion constructed to connect said wheel to the line-space wheel so as to cause the platen to rotate at a different speed from that of the line-space wheel, and means for frictionally opposing the relative rotation of the platen and the line-space wheel.

32. In a type-writing machine, the combination of a platen-frame, a platen, a line-space wheel, a wheel operated by and arranged concentrically of the line-space wheel and operatively connected to the platen, and constructed to cause the platen to turn through aliquot parts of a revolution at corresponding movements of the line-space wheel through aliquot parts of a revolution, and a frictional device arranged between the line-space wheel and the platen and constructed to oppose the movement of the platen-wheel and platen relatively to the line-space wheel.

33. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel, a toothed wheel secured thereto, a companion toothed wheel concentric therewith, means for connecting the said toothed wheels in a manner to cause the platen to rotate at a speed unequal to that of the line-space wheel, and automatically-operating means for reciprocating the platen and/or relatively to the platen-frame.

34. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel, a toothed wheel connected to the platen, a companion toothed wheel connected to the line-space wheel, all of said wheels being concentric with the platen and the said toothed wheels being of substantially equal diameter and provided with unequal numbers of teeth, a pinion arranged in mesh with both said companion wheels, so that the platen is caused to rotate at a speed unequal to that of the line-space wheel, and automatically-operating means for reciprocating the platen and/or relatively to the platen-frame.

35. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein, means for preventing lateral movement of the line-space wheel relatively to the platen-frame, a cam connected to the line-space wheel, a platen arranged concentrically with the line-space wheel and constructed to rotate relatively thereto, and means connected to the platen for engaging the cam so as to effect simultaneously an endwise reciprocation of the platen relatively to the line-space wheel.

36. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein and having a hub provided with a cam, means for preventing lateral movement of the line-space wheel relatively to the platen-frame, a platen arranged concentrically with the line-space wheel and constructed to rotate relatively thereto, a drum operatively connected to the platen and including said cam-hub, and means arranged upon the drum for engaging the cam, so that during the relative rotation of the platen and line-space wheel the platen is reciprocated endwise within the platen-frame.

37. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein and having a cam, as 58, means for preventing lateral movement of the line-space wheel relatively to the platen-frame, a platen mounted in the platen-frame concentrically with the line-space wheel, a drum, as 48, operatively connected to the platen and concentric therewith and including said cam, a wheel, as 47, secured to the open end of the drum and adjacent to the line-space wheel, a pinion, as 52, connecting the wheel 47 with the line-space wheel so as to cause variation in their angular speeds, and means arranged upon the drum for engaging the cam so as to reciprocate the platen endwise during the relative rotary movements of the platen and the line-space wheel.

38. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein and having a hub provided with a cam, means for preventing lateral movement of the line-space wheel relatively to the platen-frame, a shaft mounted in the platen-frame concentrically with the line-space wheel, a cylindrical platen mounted upon the shaft, a drum rigidly secured to the shaft and including said hub and provided with means for engaging said cam, and means for automatically effecting a relative rotation of the platen-shaft and the line-space wheel.

39. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a rotary device mounted concentrically with the platen and provided with a peripheral cam-groove, a rotary tabular device mounted concentrically with and including said cammed device, one of said devices being connected to the platen and the other thereof being fixed against endwise motion relatively to the platen-frame, and means for effecting automatically a relative rotation of the said devices.

40. In a type-writing machine, the combination of a platen-frame, a line-space wheel, a platen, means for imparting a relative rotary movement to the line-space wheel and platen, a cam secured to the line-space wheel, and means secured to the platen for engaging the cam, the construction and arrangement being such that upon relative rotation of the line-space wheel and platen the latter is moved endwise relatively to the platen-frame.

41. In a type-writing machine, the combination of a platen-frame, a rotary device, as 41, provided with a cam, a shaft including said cam device and provided with means for engaging the cam, whereby a relative lateral movement is caused by a relative rotary movement between the cam device and the shaft, a platen-cover, as 8, rotatably connected to one of said rotary devices, means for preventing lateral movement of the other of said rotary devices and means for imparting a relative rotary movement to said rotary device.

42. In a type-writing machine, the combination with a platen-frame, of a platen-cover, as 8, a shaft connected thereto, a line-space wheel, a cam fixed upon said line-space wheel and arranged within said shaft, and means operated by said cam and connected to the platen-cover for reciprocating the latter endwise relatively to the platen-frame.

43. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein, means for securing the line-space wheel against lateral movement relatively to the platen-frame, a shaft arranged concentrically with said line-space wheel, a platen mounted upon the shaft, and means for reciprocating the platen and shaft endwise relatively to the platen-frame.

44. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein, means for securing the line-space wheel against lateral movement relatively to the platen-frame, a platen mounted upon the shaft, and means for reciprocating the platen and shaft endwise relatively to the platen-frame.

45. In a type-writing machine, the combination of a platen-frame, a platen, line-spacing device, a platen-shaft and means for reciprocating the platen and the shaft endwise relatively to the platen-frame during the operation of the line-spacing device.

46. In a type-writing machine, the combination of a platen-frame, a platen, a wheel, as 47, operatively connected thereto, a line-space wheel, a pinion mounted upon the platen-frame and operatively connecting the line-space wheel to the wheel 47, and means for automatically reciprocating the platen and wheel 47 endwise relatively to the line-space wheel, the platen being constructed to remain constantly in mesh with the wheel 47.

47. In a type-writing machine, the combination of a platen-frame, a platen, a wheel, as 47, operatively connected thereto, a line-space wheel, a pinion mounted upon the platen-frame and operatively connecting the line-space wheel to the wheel 47, and means for automatically reciprocating the platen and wheel 47 endwise relatively to the line-space wheel, the platen being elongated so as to remain constantly in mesh with the wheel 47.

48. In a type-writing machine, the combination of a platen-frame, a platen, a wheel, as 47, operatively connected thereto, a line-space wheel, a wheel, as 48, rigidly connected thereto, the line-space wheel being arranged between the wheels 46 and 47, a platen mounted upon the platen-frame and connecting the wheels 46 and 47 so as to cause the relative rotation thereof, and means for automatically reciprocating the platen and wheel 47 relatively to the line-space wheel, said platen having a peripheral groove opposite the line-space wheel, and being elongated so as to remain constantly in mesh with the wheel 47.

49. In a type-writing machine, the combination of a platen-frame, a hubbing, as 45, secured to an end bar 4 thereof, a line-space wheel having a central bore and constructed to turn in said hubbing but to be held thereby against lateral motion, a shaft journaled at one end in said bore, a cylindrical platen mounted upon the shaft, and means for reciprocating the shaft and platen endwise relatively to the line-space wheel.

50. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel arranged at one end of the platen, devices arranged at the other end of the platen for adjusting at will the relative circumferential positions of the line-space wheel and platen, a thumb-wheel for actuating said adjusting device, and a brake for preventing backlash between the line-space wheel and the platen.

51. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel and platen-sweeping device arranged at one end of the platen, adjusting devices arranged at the other end of the platen for altering at will the relative circumferential positions of the line-space wheel and platen, and a thumb-wheel for actuating said adjusting device.

52. In a type-writing machine, the combination with a platen-frame, a platen, and a line-spacing mechanism, including a line-space wheel having uniformly-spaced teeth and arranged concentrically with the platen, and also including means for turning the platen through an aliquot part of a complete revolution of each portion of the line-spacing mechanism, of means for turning the platen at will without reference to the line-spacing mechanism, so as to effect an independent adjustment of the paper upon the platen.

53. In a type-writing machine, the combination of a platen-frame, a platen, a line-space wheel arranged concentrically with the platen and having evenly-spaced teeth, means for effecting automatically relative rotary movements of the platen and the line-space wheel, and means for turning the platen at will relatively to the line-space wheel, so as to adjust the paper carried thereon.

54. In a type-writing machine, the combination with a cylindrical platen and a line-space wheel of an intermediately-arranged finger-wheel rotatable relatively to the platen, means controlled by said finger-wheel for turning the platen relatively to the line-space wheel, and means for causing an automatic relative rotation of the platen and line-space wheel at the operation of the latter.

55. In a type-writing machine, the combination of a cylindrical platen, a line-space wheel connected thereto by means of adjusting device, and a finger-wheel, the construction and arrangement being such that at the operation of said line-space wheel the platen rotates automatically relatively to the line-space wheel, and also such that said finger-wheel may be operated to cause an independent rotary movement of the platen in either direction relatively to the line-space wheel.

56. In a type-writing machine, the combination of a cylindrical platen, a line-space wheel, a finger-wheel for rotating the platen and line-space wheel simultaneously, means for causing an automatic relative rotation between the line-space wheel and the platen at each simultaneous rotation, a finger-wheel rotatable relatively to the platen, and means controlled by the last-mentioned finger-wheel for rotating the platen relatively to the line-space wheel.

57. In a type-writing machine, the combination of a platen-frame, a cylindrical platen, a line-space wheel, a finger-wheel arranged at each end of the platen-frame for rotating the platen and line-space wheel simultaneously, means for causing an automatic relative rotation between the line-space wheel and the platen at each simultaneous rotation, a third finger-wheel, and means controlled by said third finger-wheel for turning the platen at will relatively to the line-space wheel so as to effect an adjustment of the paper carried by the platen.

58. In a type-writing machine, the combination of a platen, a line-space wheel, and toothed gearing positively connecting the line-space wheel to the platen, said gearing being constructed and arranged so that at the rotation of the line-space wheel the platen rotates relatively thereto, and also so that the platen may at will be rotated by said gearing independently of the line-space wheel, in order to effect an adjustment of the paper.

59. In a type-writing machine, the combination of a platen-frame, a platen, a line-space wheel, means for automatically reciprocating the platen in lateral-space direction relatively to the platen-frame, and means for turning the platen at will relatively to the line-space wheel.

60. In a type-writing machine, the combination of a platen-frame, a platen, a line-space wheel having evenly-spaced teeth, means for effecting automatically relative rotary movements of the platen and the line-space wheel, means for automatically reciprocating the platen endwise relatively to the platen-frame, and means for turning the platen at will relatively to the line-space wheel, so as to adjust the paper carried thereon.

61. In a type-writing machine, the combination with a platen and a line-space wheel, of two trains of differential gearing, each train constructed to cause relative rotation of the platen and the line-space wheel, one train constructed to be manually operated for adjusting the paper carried upon the platen, and the other train being constructed to operate automatically.

62. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein, and a platen connected to the line-

space wheel by two trains of gears, one train being constructed to operate automatically at the line-spacing operation and the other train being manually operable for effecting an adjustment of the paper carried by the platen.

63. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein, a relatively rotatable platen, and two brakes, as 57 and 51, arranged in series between the platen and the line-space wheel.

64. In a type-writing machine, the combination of a platen-frame, a line-space wheel mounted therein, and a platen connected to the line-space wheel by two trains of gears arranged in series, each train being provided with a brake for preventing backlash between the line-space wheel and the platen.

65. In a type-writing machine, the combination of a platen frame, a line-space wheel mounted therein, and a platen connected to the line-space wheel by two trains of gears, one train being constructed to operate automatically at the line-spacing operation and the other train being manually operable for effecting an adjustment of the paper carried by the platen, each train being provided with a brake for preventing backlash between the line-space wheel and the platen.

66. In a type-writing machine, the combination of a metallic platen-tube, a roller tubular sheath therefor, insulating-plugs arranged in the ends of the metallic tube, retaining-curves seated in the metallic tube and engaging the plugs, and suitable central supports for the plugs.

67. In a type-writing machine, the combination of a metallic platen-tube, a roller tubular sheath therefor, insulating-plugs arranged in the ends of the metallic tube, retaining-curves seated in the metallic tube and engaging the plugs, metallic bushings arranged centrally in said plugs, and a shaft upon which said bushings are supported.

68. In a type-writing machine, the combination of a metallic platen-tube, a roller tubular sheath therefor, insulating-plugs arranged in the ends of the metallic tube, retaining-curves seated in the metallic tube and engaging the plugs, metallic bushings arranged centrally in said plugs, and a shaft upon which said bushings are supported.

69. In a type-writing machine, the combination of a cylindrical platen, an insulating-plug therefor firmly secured to a central sleeve, said sleeve being arranged upon a shaft, and means for causing the sleeve to rotate either together with the shaft or independently thereof.

70. In a type-writing machine, the combination of a cylindrical platen, an insulating-plug therefor firmly secured to a central sleeve, said sleeve being arranged upon a shaft and frictionally engaged thereto, and means for rotating the sleeve at will in opposition to said friction.

71. In a type-writing machine, the combination of a line-space wheel, a cylindrical platen-body, an insulating-plug at each end thereof, a central sleeve secured in one of said plugs, said sleeve being mounted upon a shaft and said shaft being connected to the line-space wheel, a planet-wheel arranged upon said sleeve, a wheel secured upon said shaft and meshing with said planet-wheel, and a manually-operated wheel for operating said planet-wheel.

72. In a type-writing machine, the combination of a line-space wheel, a cylindrical platen-body, an insulating-plug at each end thereof, a central sleeve secured in one of said plugs, said sleeve being mounted upon a shaft and said shaft being connected to the line-space wheel, a planet-wheel arranged upon said sleeve, a wheel secured upon said shaft and meshing with said planet-wheel, a manually-operated wheel for turning said planet-wheel, and a brake for opposing the rotation of said sleeve upon said shaft.

73. In a type-writing machine, the combination of a cylindrical platen, a platen-frame, wheel 46, wheel 47 connected to the platen, a rotary device connecting said wheels and operated by wheel 46, and means for reciprocating wheel 47, together with the platen, toward and away from wheel 46.

74. In a type-writing machine, the combination of a cylindrical platen, a platen-frame, wheel 46, wheel 47, an elongated pin in mesh with wheel 47 and operated by wheel 46, and means for reciprocating wheel 47, together with the platen, toward and away from wheel 46.

75. In a type-writing machine, the combination of a platen, a toothed wheel connected thereto, a line-space wheel, a toothed wheel connected to the line-space wheel, one of said toothed wheels having more teeth than the other, and a platen meshing with both of said toothed wheels.

76. In a type-writing machine, the combination with a platen, of a line-space wheel connected thereto by a differential gearing; said differential gearing including two connected toothed wheels having different numbers of teeth, one of said toothed wheels being connected to the platen and the other of said toothed wheels being connected to the line-space wheel, and means for causing one of said toothed wheels to creep relatively to the other wheel so as to alter the relative relative positions of the line-space wheel and platen.

698,152. CHAR-CUTTER AND MATCH-SAFETY. JAMES F. TAYLOR, Fort Worth, Tex. Filed Dec. 11, 1901. Serial No. 95,000. (No model.)

Claim.—1. A match-cut and cigar-cutter comprising a suitable box, a plate forming a part of the front wall of said box and projecting within said box and supported against the back wall of said box, a blade passing through said plate and supported thereon for shifting matches and cutting cigars, said plate having an opening for inserting cigars and said blade being flush with said plate and having a cutting edge adapted to pass under said plate and across said opening, and a tongue integral with said blade for operating the same.

2. A match-cut and cigar-cutter comprising a box having a match-receptacle therein, a plate forming a part of the front wall of said box and projecting through said box to and against the back wall thereof, a blade passing through said plate and having parts of each of the flat surfaces thereof flush with said plate, the upper part of said blade forming a match-shifter and the lower part thereof forming a cigar-cutter, said plate having an opening for inserting the tips of cigars and said blade having a cutting edge adapted to cross said opening, and means for operating said blade.

3. A match-cut and cigar-cutter comprising a box having a match-receptacle therein, a plate forming a part of the front wall of said box and projecting within said box, a spring-pressed blade passing through and supported on said plate, the upper part of said blade forming a match-shifter and the lower part having an edge for cutting cigar-tips, said plate being flush with said blade and having an opening across which said cutting edge moves when said blade is operated, a set-screw for securing said blade in a position flush with said plate projecting through a slot in said blade and secured into said plate, and a tongue for operating said blade projecting through a slot in said plate.

4. A match-cut and cigar-cutter comprising a box having a match-receptacle therein and having suitable openings through which only one match can be taken at one time, a plate forming a part of the front wall of said box and projecting in and supported against the back wall thereof, a blade having the upper part thereof notched for shifting matches and having a cutting edge adapted to pass across an opening in said plate, said blade having parts of its surface flush with parts of the surface of said plate, and means for securing said blade consisting of a lag integral with said plate, a set-pin projecting through a slot in said plate and riveted in said blade, a spring attached to said lag and to said set-pin for holding said blade in its normal position, and a tongue integral with said blade.

5. A match-cut and cigar-cutter comprising a box having a match-receptacle therein and having suitable openings for permitting the taking out of one match at one time, a plate forming a part of the front wall of said box and projecting at an angle through and to the back wall of said box, a blade having a cutting edge adapted to pass across an opening in the outer part of said plate, said blade passing through said plate and the upper part thereof forming a match-shifter, and means for operating said blade, said plate and said blade forming the bottom of the match-receptacle and said blade being narrower than said plate whereby the match-heads will not come in contact with said blade while being shifted.

6. A match-cut and cigar-cutter comprising a box having a match-receptacle therein and having suitable openings for permitting the taking

out of one match at a time, a plate forming a part of the front wall of said box and projecting at an angle through and to the back wall of said box, a blade having a cutting edge adapted to pass across an opening in the wall part of said plate, said blade passing through said plate whereby the part of said blade having said cutting edge passes under said plate and flush therewith and the other part of said blade passes above said plate and flush therewith, the part of said blade above said plate being adapted to shift matches and being narrower than said plate whereby the match-heads will not come in contact with any friction-surfaces while being shifted.

698,158. CULTIVATOR. THOMAS R. TERRY, Jamestown, N. Y. Filed Feb. 14, 1902. Serial No. 94,001. (No model.)

Claim.—1. In a cultivator having a central beam and laterally-adjustable side beams, means for adjusting said side beams including a spring-supported handle and connections between the same and the side beams whereby the latter are actuated by the movement of the handle.

2. In a cultivator having a central beam and laterally-adjustable side beams, means for adjusting said side beams comprising a spring-supported handle, hinged connections between the side and central beams, and a lever mechanism between the handle and the side beams for adjusting the latter by the movement of the former.

3. In a machine of the character described, the combination of laterally-movable spring-pressed side beams, a vertically-movable handle, and connections between the handle and beams for moving the latter transversely when the handle is moved vertically.

4. In a machine of the character described, the combination with laterally spring-supported, normally elevated side beams, of a movable handle and means interposed between the handle and beams for moving the latter laterally by power derived from the former.

5. In a cultivator the combination with a central beam and pivotally-mounted side beams, of a movable handle, a spring-support therefor tending to normally elevate the same, hinged connections between the side and central beams, a slide on the central beam and connections between the slide and the said hinged connections, and a lever mechanism between the handle and the slide whereby the depression of the handle operates the lever connections and slide and moves the side beams outwardly.

6. In a cultivator, the combination of the central beam and the laterally-movable side beams, hinged connections between the beams, a slide on the central beam and links connecting the same with the hinged connections, a vertically-movable handle having a yoke, a pin passing from the central beam into the yoke, a spring compressing the pin and bearing upwardly against the yoke, to normally elevate the handle, a bell-crank lever having one part connected to the yoke, a toothed bar connected to another part of said lever, and a second lever fulcrumed between its ends, having one end connected to said slide and the opposite portion engaged by said toothed bar whereby the movement of the handle is transmitted to the side beam to expand the latter.

7. In a cultivator, the central and side beams, in combination with wide hinged plates between the beams, said plates standing on edge and provided with sockets to receive the hinged-plates, and caps removably fitting the sockets.

698,154. WASHING-MACHINE. ABRAHAM S. THOMAS, Worcester, Mass. Filed Dec. 22, 1901. Serial No. 94,002. (No model.)

Claim.—1. In a washing-machine, the combination of a receptacle provided with an aperture, a support, an L-shaped arm depending from the support and extending through the aperture of the receptacle from the exterior thereof, a rotating device passing through the support and detachably engaging the inner end of the arm and causing the support to the tub, said support being adapted to be swung backward and upward, and washing mechanism mounted on the support, substantially as described.

2. In a washing-machine, the combination of a receptacle provided with an aperture, a support arranged upon the receptacle, arms depending from the support and extending inward through the aperture from the exterior thereof, means for engaging the terminals of the arms for producing

venting the same from being withdrawn from the aperture, and washing mechanism mounted on the support, substantially as described.

698,155. COUPLING FOR WIRES. ROLLAND THOMPSON, New York, N. Y., assignor of one-fourth to Wesley S. Thompson, New York, N. Y. Filed Feb. 1, 1902. Serial No. 93,171. (No model.)

Claim.—1. A coupler for wires comprising a single coupling-bar, provided with a loop at each end and extending inwardly approximately two-thirds the length of the coupler, said bars being parallel with each other and slightly separated to provide a well, and one or more tapering cut-overs between the lapped portions of the wires, as set forth.

2. The combination with wires, of a coupling-bar having therein holes at opposite ends, each of which extends into the bar slightly to one side of the axial line, and having a wall between them, and one or more tapering cut-overs between the lapped ends of the wires passing through the separating-wall, as set forth.

698,156. SYSTEM OF ELECTRIC DISTRIBUTION. BLANK THOMAS, Lynn, Mass., assignor to the Thomson-Houston Electric Company, a Corporation of Connecticut. Filed Nov. 2, 1901. Serial No. 101,600. (No model.)

Claim.—1. In a system of electric distribution, a series of secondary circuits of induction coils supplying arc-lights or other devices, the primary coils of which induction coils are multiple-arc branches of a single primary circuit, or set of main A, B, through which alternating or reversed currents are flowing, as described.

2. In a system of electric distribution, a set of main A, B, supplied by alternating currents, or alternating electrical impulses, rendering said main alternately positive and negative with respect to each other, in

combination with branch circuits taken from said main at convenient points, and finally carried through the primary wind or coils of a set or series of induction-coils, the secondaries of which are connected to electric lamps, or other apparatus, for utilizing the impulses generated in said secondaries by induction from the said primary.

3. In a system of electric distribution, the combination with the high-potential main through which alternating or reversed currents are flowing, of electric converters or reducers connected in multiple between said main, and inductance lamps or other transmitting devices supplied from said reducers with currents of lower tension and greater quantity than those circulating in the main circuit-coil of the converter.

698,157. PHOTOGRAPHIC FILM ROLL AND ROLL-HOLDER.
JOHN E. TUNNICLIFFE, Manchester, England. Filed Mar. 20, 1900. Serial No. 1,468. (No model.)

Claim.—1. A holder for photographic film comprising in its construction a reel of two D-shaped pieces of sheet metal, having the flat sides placed and secured together, in combination with a sheet-metal supporting-frame with ends provided with slots, into which the open ends are fitted free to rotate therein, substantially as described.

2. A reel for photographic film comprising in its construction two D-shaped pieces of sheet metal with their flat sides placed face to face, and two flanges by which they are secured together substantially as described.

3. In a holder for photographic film, the combination with a metallic frame or holder stamped from sheet metal, and provided with up-turned ends of a sheet-metal reel provided with longitudinal slots and fitted into apertures in the ends of the holder, so as to rotate therein, substantially as described.

4. A photographic-film holder comprising in its construction, the holder B provided with stiffening-grooves, the up-turned ends b provided with apertures and stiffening-grooves, and the reel A formed of two D-shaped pieces of sheet metal, the ends d of which are fitted into the apertures in the holder ends b and provided with longitudinal slots D' between the two parts, substantially as described.

698,158. ELECTRIC CLOCK-WINDING MECHANISM. ALBERT TRUMB, Chicago, Ill. Filed Jan. 27, 1901. Serial No. 65,404. (No model.)

Claim.—1. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, a contact-stud carried by said counter-shaft, a flexible contact adapted to have electrical engagement with said contact-stud, and means moving in unison with the armature of the winding mechanism for pushing the flexible contact away from each electrical contact with the contact-stud, substantially as set forth.

2. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, a contact-stud carried by said counter-shaft, a flexible contact adapted to have electrical engagement with said contact-stud, and an arm moving with the armature of the winding mechanism and adapted to push the flexible contact away from its electrical contact with the contact-stud, substantially as set forth.

3. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, an insulating-stud and a contact-stud carried by said counter-shaft, a flexible contact adapted to have engagement with said stud, and means moving in unison with the armature of the winding mechanism for pushing the flexible contact away from its electrical contact with the contact-stud, substantially as set forth.

4. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, an insulating-stud and a contact-stud carried by said counter-shaft, a flexible contact adapted to have engagement with said stud, and an arm moving with the armature of the winding mechanism and adapted to push the flexible contact away from its electrical contact with the contact-stud, substantially as set forth.

5. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, a contact-stud carried by said counter-shaft, a flexible contact, the same comprising a vibratory spring-arm and a pivoted spring-finger on the free end of said arm, adapted to have electrical engagement with said contact-stud, and means moving in unison with the armature of the winding mechanism for pushing the flexible contact away from its electrical contact with the contact-stud, substantially as set forth.

6. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, a contact-stud carried by said counter-shaft, a flexible contact, the same comprising a vibratory spring-arm and a pivoted spring-finger on the free end of said arm, adapted to have engagement with said contact-stud, and an arm moving with the armature of the winding mechanism and adapted to push the flexible contact away from its electrical contact with the contact-stud, substantially as set forth.

7. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, an insulating-stud and a contact-stud carried by said counter-shaft, a flexible contact, the same comprising a vibratory spring-arm and a pivoted spring-finger on the free end of said arm, adapted to have engagement with said stud, and means moving in unison with the armature of the winding mechanism for pushing the flexible contact away from its electrical contact with the contact-stud, substantially as set forth.

8. In an electromagnetic clock-winding mechanism of the character herein described, the combination with the intermittent winding mechanism, the main shaft, a counter-shaft geared with and receiving increased movement from the main shaft, an insulating-stud and a contact-stud carried by said counter-shaft, a flexible contact, the same comprising a vibratory spring-arm and a pivoted spring-finger on the free end of said arm, adapted to have engagement with said stud, and an arm moving with the armature of the winding mechanism and adapted to push the flexible contact away from its electrical contact with the contact-stud, substantially as set forth.

698,159. UNIVERSAL JOINT. ABRAHAM VANHORN, Hartford, Conn. Filed Mar. 12, 1901. Serial No. 51,908. (No model.)

Claim.—1. In a connection the two bifurcated shafts, the four transverse shafts removably but non-rotatably secured thereto, and an intermediate block having four transverse shaft bearing-sockets, all substantially as described and for the purposes set forth.

2. In combination the two bifurcated shafts, a transverse shaft removably but non-rotatably secured to each fork, an intermediate block having sockets adapted to the shape of the transverse shafts, and also adapted to move back and forth thereon.

3. In combination the bifurcated shafts, a transverse shaft removably attached to each fork, interlocking parts on each transverse shaft and the fork to which it is attached, and an intermediate block having sockets adapted to receive the transverse shafts, substantially as described.

4. In combination the two bifurcated shafts, a transverse shaft secured to each fork thereof by means of a screw, projections on the transverse shafts adapted to enter recesses in the fork, an intermediate block having sockets adapted to the shape of the transverse shafts and arranged to connect said shafts, substantially as described.

5. In combination the two bifurcated shafts, the transverse shafts in the form of transverse cones removably secured to the said forks, an intermediate block having conical sockets adapted to receive and work on said transverse shafts, the parts being so arranged that the apices of the conical transverse shafts meet at substantially the center of the intermediate block, substantially as described.

698,160. ACETYLENE-GAS GENERATOR. GEORGE F. WATSON, Chicago, Ill. Filed Sept. 4, 1901. Serial No. 74,576. (No model.)

Claim.—1. In a carbide-feeding apparatus for acetylene-gas generators, in combination, a carbide-receptacle above the generator, an opening therein through which the carbide is adapted to fall, a tilting cup below the opening discharging from each side alternately into the generator, and means connected with the bell of the generator to cause the cup to tilt according to the rise and fall of the bell.

2. In an acetylene-gas apparatus, in combination, a generator, a gasometer, a carbide-supply receptacle above the generator, an opening therein through which the carbide is adapted to fall, a tilting cup below the opening having two compartments one of which is adapted to discharge carbide into the generator when the cup is tilted in one direction and the other when tilted in the other direction, and means connected with the bell of the generator to cause the cup to tilt according to the rise and fall of the bell.

3. In an acetylene-gas apparatus, in combination, a generator, a gasometer, a carbide-supply receptacle, an opening therein through which carbide is adapted to fall, a tilting cup below the opening having two compartments discharging alternately into the generator, a rock-shaft adapted to cause the cup to tilt, and means connected with the bell of the generator to rock the shaft.

4. In an acetylene-gas apparatus, in combination, a generator, a carbide-supply receptacle, an intermediate feeding device therefrom which

carbide is adapted to be delivered into the generator, a normally closed valve between the feeding device and the generator and means to automatically open the valve simultaneously with the delivery of the carbide.

5. In an acetylene-gas apparatus, in combination, a generator, a gasometer, a carbide-supply receptacle having an opening through which carbide is adapted to be discharged, a tilting cup below the opening, a funnel below the tilting cup adapted to receive the carbide discharged therefrom, a normally closed valve at the lower end of the funnel, means to automatically open the valve at the fall of the carbide, and means connected with the bell of the generator to operate the tilting cup.

6. In an acetylene-gas apparatus, in combination, a generator, a gasometer, a carbide-supply receptacle, a feed-opening therein, a spring-actuated tilting cup below the opening, having a plurality of compartments, each alternately filling from the supply-receptacle and discharging into the generator, and means connected to the bell of the generator to cause the spring to tilt the cup according to the rise and fall of the gasometer-bell.

7. In an acetylene-gas apparatus, in combination, a generator, a gasometer, a carbide-supply receptacle, an opening therein through which carbide is adapted to fall, a tilting cup below the opening adapted to discharge carbide into the generator, a rock-shaft adapted to cause the cup to tilt, means connected to the rock-shaft to operate the same by the rise and fall of the gasometer-bell, and means to disconnect the rock-shaft from said means and to operate the rock-shaft otherwise.

8. In an acetylene-gas apparatus, in combination, a generator, a gasometer, a carbide-supply receptacle, a feeding device therefrom, a funnel below the feeding device through which the carbide is adapted to fall into the generator, a valve at the mouth of the funnel, a rock-shaft extending into the funnel, means to rock the shaft according to the rise and fall of the gasometer-bell, and means connected with the shaft to operate the valve.

698,161. COMBINED POKER AND LIFT-LIFTER. HARRY WATSON, Chicago, Ill. Filed July 14, 1901. Serial No. 65,405. (No model.)

Claim.—1. In a combined poker and stove-lid lifter, the combination with the poker-rod and its handle, of a sliding sleeve mounted on said rod and held against axial movement thereon, said sleeve being provided with a stove-lid lifting-blade, a stop upon the rod to limit the outward movement of the sleeve, and a catch upon the handle to hold the sleeve in retracted position, substantially as described.

2. In a combined poker and stove-lid lifter, the combination with a poker-rod provided at one end with a handle and having the other side of its opposite end beveled, a sleeve slidably mounted on the rod and held against axial movement thereon and provided with a stove-lid lifting-blade and a pin, a stop upon the rod to limit the outward movement of the sleeve to hold the blade in proper relative position to the beveled surface of the rod, and a spring-catch upon the handle to engage said pin to hold the sleeve retracted, substantially as described.

698,162. **PLIERS AND GRIPPING-TOOL.** HERMAN S. WHELAN, New York, N. Y. Filed May 11, 1901. Serial No. 90,578. (No model.)

Claim.—1. In parallel pliers, increased primary levers and crossed secondary levers, working in conjunction with each other, all equipped to close the jaws upon the closing of the hand-levers, substantially as set forth.

2. Parallel pliers with increased primary and crossed secondary levers engaged with jaw-carrying members suspended within the said primary and secondary levers, all equipped with means and seating with said means to produce parallel movements of the said members toward each other or away from each other, relatively, upon the respective closing or opening of the hand-levers, substantially as set forth.

3. In parallel pliers, one of primary and secondary levers, one of which is moved while the other is increased, jaw-carrying members suspended within each lever parallel to each other, by means of pins, slots in the said members through which connection is made between the said secondary levers at one extremity and in pivotal connection at the other extremity by means of the said pins, the said secondary levers joined by a fulcrum-pin, all arranged for simultaneous action and to give the members a parallel motion, one toward the other as the primary levers are pressed together, substantially as set forth.

4. In parallel pliers, increased primary levers, each lever independent of its companion by direct connection, working in conjunction with crossed secondary levers, their lower extremities connected by pins through slots carried in the primary levers and in jaw-carrying members and their upper extremities pivotally pivoted to each other, in pairs, and to the said members, the primary levers connected to the said members by their upper extremities and imparting motion to the said members and secondary levers by means of slots, all arranged to force the jaws carried on the said members toward each other upon the closing of the primary levers, and to keep them in parallel position at all times, substantially as set forth.

5. In parallel pliers, levers attached to jaw-carrying members, wire-grips attached to the said members on their faces and extending beyond the plane of the levers, substantially as set forth.

6. In parallel pliers, levers engaged with jaw-carrying members equipped with gripping-jaws carried in sets mounted upon the faces of the said members, and extending outwardly therefrom beyond the plane of the said levers, all equipped to insure parallel movements of the said members and jaws, substantially as set forth.

7. In parallel pliers, jaw-carrying members equipped with a plurality of parallel-moving jaws, the auxiliary jaws extending beyond the plane of levers connected to the said members, so as to give an unobstructed opening for the introduction of a wire or other substance into the said auxiliary jaws, all equipped to insure the parallel movement of the several sets of jaws, substantially as set forth.

698,163. **PROCESS OF REFINING SPELTER.** CHARLES WHELAN, New York, N. Y. Filed Apr. 20, 1901. Serial No. 87,917. (No specimens.)

Claim.—1. The process of refining spelter which consists in treating the melted spelter with phosphorus.

2. The process of refining spelter which consists in treating the melted spelter with phosphorus and with magnesium.

3. The process of refining spelter which consists in treating the melted spelter with boron, phosphorus and magnesium.

698,164. **PHOTOGRAPHIC CAMERA.** JOHN WHELAN and ALFRED WHELAN, Manchester, England. Filed Feb. 1, 1902. Serial No. 92,128. (No model.)

Claim.—1. In photographic camera having two chambers one for the reception of a spool with the film on which the pictures are intended to be taken, and one for the spool on which the film is wound after the picture has been taken the mechanism by which the spools can be placed in said chambers, retained therein, opened and removed therefrom, consisting of semicircular rods *d*, *e* and *f* in combination with spools with disks at their ends which have one or more projections on or near their edges, substantially as and for the purpose hereinafter described.

2. A film-carrying spool for a camera having flat disks on its ends and a projection at the outer edge of the disks, in combination with a rotatable disk, adapted to bear against said flat end to rotate it, substantially as described.

3. A photographic camera having a spool with disks at its ends and semicircular rods in which the disks are adapted to be placed and means for rotating the spool, substantially as described.

4. A photographic camera having a spool with disks at its ends, semicircular rods in which the disks are adapted to be placed and register in the rods, substantially as described.

5. A photographic camera having a spool with disks, semicircular rods, rotatable disks in the rods, means to rotate them, and a spring means for holding said rotatable disks against the spool ends, substantially as described.

698,165. **APPARATUS FOR BORING SHAFTS.** EDWARD ABE, Aachen, Germany, assignor to Fried. Krupp, Essen, Germany. Filed Nov. 26, 1901. Serial No. 93,496. (No model.)

Claim.—In an apparatus for boring shafts, the combination of a shaft or beam, a footpiece rigidly secured to said shaft and provided with trapezoidal, side stays of triangular construction resting with their bases upon said footpiece and secured thereto, and cross-pieces rigidly connected with said shaft and with said stays, substantially as described.

698,166. **CORSET.** JAMES C. ANDREWS, Springfield, Mass., assignor to the Bay State Corset Co., Springfield, Mass., a Corporation. Filed Sept. 14, 1901. Serial No. 78,465. (No model.)

Claim.—The combination is a corset having vertically-arranged stanchions extending nearly to the upper edge thereof, of a binding-strip secured to the upper edge of the corset by a line of stitches above the ap-

per ends of said stanchions, said binding-strip formed with a flap extending downward on the face of the corset over the upper ends of said stanchions, and an ornamental strip secured to the corset between the binding-strip and the face thereof, substantially as described.

698,167. **BOWEN.** JOHN F. ATTLEY, Chicago, Ill. Filed Dec. 11, 1900. Serial No. 730,916. (No model.)

Claim.—1. In a mower, the combination with the main frame, finger-beam and coupling-bar, of means for exerting a constant lifting tendency on the finger-beam, said means comprising a lifting-spring connected to the frame, a bell-crank pivotally mounted on the coupling-bar, a connection between one arm of the bell-crank and the spring, and a connection between the other arm of the bell-crank and the finger-beam, and a lifting-lever connected to that arm of the bell-crank to which the lifting-spring is connected, but at a point further from the pivot of the bell-crank, said lifting-lever being normally inactive, but adapted when operated, to exert with the spring in lifting the beam, but with a greater leverage, substantially as described.

2. In a mower, the combination with a main frame and finger-beam hinged thereto, of a quadrant pivoted on the main frame, a spring flexibly connected to the main frame and to said quadrant, a bell-crank lever pivoted on the finger-beam coupling, a link connecting the quadrant and one arm of the bell-crank, and a link connecting the other arm of the bell-crank and the finger-beam, a lifting-lever pivoted on the main frame, a double-armed lever pivoted on the quadrant and connected between the double-armed lever and the lifting-lever and between the double-armed lever and the bell-crank, the latter connection being to the same arm to which the spring is connected but further from the pivot of the bell-crank, and a stop for limiting the double-armed lever to the quadrant whereby the spring has a tendency to lift the outer end of the finger-beam, while the lever is normally inactive but exerts with the spring to lift the beam clear of the ground, substantially as described.

3. In a mower, the combination with the main frame, of a flexing finger-beam hinged thereto, spring connections between the main frame and the finger-beam, the spring whereof is connected directly with the frame and exerts a constant tendency to lift the beam, a lever pivoted on the main frame and forming an element of the said spring connection and to which the spring is directly connected, a draft-rigging and a non-elastic connection directly joining the draft-rigging and said pivoted lever whereby the power of the draft-animals is applied directly to the lifting of the finger-beam, substantially as described.

698,168. **WINDOW-LAMP.** PAUL RABENAU, San Francisco, Cal. Filed Oct. 22, 1901. Serial No. 90,904. (No model.)

Claim.—1. The combination with a sash, of shoes at the side edges thereof, pivots supporting the sash in said shoes, a retaining device for normally holding said sash and shoes in alignment, consisting of a tube, springs normally holding said tube in operative position, and means limiting the extent to which said tube may move under the action of said springs, substantially as described.

2. The combination with a sash, of shoes adapted to fit against the stile thereof, pivots connecting said shoes and stile, whereby the sash may swing to an angular position with reference to said shoes, a retaining device between one of said stiles and the shoe adjacent thereto, said retaining device consisting of a tube carried by one of said members, as the stile, and adapted to project to engage the other of said members, as the shoe, to hold said members in alignment, springs for holding said tube normally in operative position, and means limiting the extent to which said tube may project, substantially as described.

3. The combination with a sash, of shoes adapted to fit against the stile thereof, pivots connecting said stile to said shoes, a retaining device carried in one of said members, as the stile, and adapted normally to hold said members in alignment, a slot through which said retaining device is adapted to project to engage the other member, and springs for projecting said retaining device through said slot, substantially as described.

4. The combination with a sash, of shoes adapted to fit against the stile thereof, pivots connecting said stile to said shoes, a retaining device carried in one of said members, as the stile, and adapted normally to hold said members in alignment, a slot through which said retaining device is adapted to project to engage the other member, said retaining device having a convex surface adapted to project through said slot, and springs for projecting said retaining device through said slot, substantially as described.

5. The combination with a sash, of shoes adapted to fit against the stile thereof, pivots connecting said stile to said shoes, a tubular retaining device carried in one of said members, as the stile, and adapted normally to hold said members in alignment, a slot through which said retaining device is adapted to project to engage the other member, and springs for projecting said retaining device through said slot, substantially as described.

6. The combination of a stile for window-casings, having internal edges spaced apart forming a narrow passage or slot, a tubular retaining device mounted in said slot, the diameter of said retaining device being somewhat greater than the width of said slot, means for yieldingly holding said retaining device in said slot, and a shoe pivoted to said slot and having a recess adapted to receive the projecting portion of said retaining device, substantially as described.

7. The combination of a stile having a narrow slot, a retaining device having a convex portion adapted to project through said slot, means for yieldingly holding said retaining device in said slot, and a shoe having a recess adapted to receive the projecting portion of said retaining device, substantially as described.

8. The combination of a stile, a shoe adapted to fit against said stile and pivotally connected thereto, a retaining device carried in one of said members and adapted to project through a suitable slot in said member, to engage the other member and hold said members in alignment, and means for yieldingly holding said retaining device in said slot, substantially as described.

9. The combination of a stile having internal edges 20, forming slots 21, a box 22 having internal edges 23 adapted to fit into said slots 21, a tube 24 carried by said box 22, said tube being adapted to project between the internal edges of the stile, springs for holding said tube 24 in operative position, a shoe pivotally connected to said stile, said shoe having a recess 45 adapted to receive the projecting portion of said tube 24 when the shoe and stile are in alignment, and means for attaching the shoe to the depending flange of the window-frame, substantially as described.

10. The combination of a stile having internal edges 20 forming grooves 21, a box 22 having internal edges 23 adapted to fit into said grooves 21, a tube 24 carried by said box 22, said tube being adapted to project between the internal edges of the stile, springs for holding said tube 24 in operative position, a shoe pivotally connected to said stile, said shoe having a recess 45 adapted to receive the projecting portion of said tube 24 when the shoe and stile are in alignment, a plate 46 having flanges

47, and grooves 44 in said shoe adapted to receive nut 48, and substantially as described.

11. The combination of a shoe, a stile pivotally secured thereto, means for normally holding said shoe and stile in alignment, and a catch carried by said shoe and adapted to engage the window-frame, to prevent upward movement of said shoe while the parts are being assembled, substantially as described.

12. The combination of a shoe, a stile pivotally secured thereto, means for normally holding said shoe and stile in alignment, a hook carried by said shoe and adapted to engage the window-frame, to prevent upward movement of said shoe while the parts are being assembled, and a spring for normally holding said hook out of operative position, substantially as described.

13. A stile for window-cases having a narrow slot, a spring-pressed strip having a portion adapted to project through said slot, the extreme width of said strip being greater than that of said slot, and means for yieldingly holding said strip in said slot, substantially as described.

14. The combination with a pivoted case and parts to which the case is pivoted, of a spring-pressed strip carried in one of said members, so the stile, said member which carries the said strip being provided with a recess to receive the same, which recess has a slot through which the strip is adapted to project to engage the other member, substantially as described.

15. A stile for window-cases having internal edges spaced apart to form a narrow passage or slot, in combination with a spring-pressed strip located in said stile, the said strip being somewhat wider than the slot and adapted to project through the same, substantially as described.

16. The combination with a stile having internal edges 30, forming slots 31, a box 32 having internal edges 33, adapted to fit into said slots 31, and a spring-pressed strip located within said box, said strip being wider than the slot and being adapted to project through said slot between the internal edges of the stile, substantially as described.

698,169. METAL CAN OR RECEPTACLE FOR PACKING SOAP OR OTHER SOLUBLE MATERIALS. FRANKLIN L. BARTON, Birmingham, England. Filed Aug. 9, 1901. Serial No. 71,408. (No model.)

Claim.—1. A can having perforated sides and an opening within one end of its body and a cover which has a recessed portion to fit within said opening and the margin of which projects around and beyond the exterior of the body in the form of a nose, substantially as herein described.

2. A can having perforated sides and having within one end of its body an opening the edge of which is turned inward in the form of a recessed socket and the margin of which projects around and beyond the exterior of the body in the form of a nose, substantially as herein described.

698,170. HOT-AIR FURNACE. WILLIAM E. BROS. FRANKLIN, Pa. Filed July 5, 1901. Serial No. 67,102. (No model.)

Claim.—1. A hot-air furnace comprising a casing having on one side of the same a fire-pot and on the opposite side an exit for the products of combustion, a plurality of vertically-disposed hot-air tubes carried by top and bottom plates, a dome or top for the reception of the heated air, and a perforated bulk or heat-retaining plate located within the casing and positioned near the opening for the exit of the products of combustion from the fire-pot, substantially as shown.

2. In a hot-air furnace the combination with a casing having on one side a fire-pot and opposite thereto an opening for the exit of the products of combustion said casing containing a plurality of hot-air tubes, a heat-retaining plate located within the casing and provided with numerous

apertures the combined area of said apertures exceeding the area of the opening for the products of combustion, substantially as shown.

3. In a hot-air furnace, the combination of a casing which is rectangular in cross-section, rectangular plates having attached thereto hot-air tubes, a dome or top for the reception of the heated air carried by the upper rectangular plate, an apertured heat-retaining plate positioned between the tubes and extending from the bottom to the top wall of the rectangular casing, an opening for the escape of the products of combustion located near the lower portion of the furnace and a fire-pot which opens into the casing on the opposite side from the escape-opening, substantially as shown.

698,171. APPARATUS FOR MANUFACTURING CHEMICAL TUBES. ERIC BORN, Düsseldorf, Germany. Filed June 2, 1901. Serial No. 68,748. (No model.)

Claim.—1. In a machine for manufacturing conical tubes from tapering strips the combination with mandrels of different diameters, of a slide carrying said mandrels, means for axially moving said mandrels, means for moving said slide at right angles to the movement of the mandrels, and means for holding said strips, substantially as and for the purpose described.

2. In a machine for manufacturing conical tubes from tapering strips the combination with mandrels of different diameters, of a slide carrying said mandrels, means for axially moving said mandrels, means for moving said slide at right angles to the movement of the mandrels, checks

for holding said strips, and means for approaching said checks, substantially as and for the purpose described.

3. In a machine for manufacturing conical tubes from tapering strips the combination with mandrels of different diameters, of a slide carrying said mandrels, means for axially moving said mandrels, means for moving said slide at right angles to the movement of the mandrels, checks for holding said strips, means for approaching said checks being articulated in their supports, substantially as and for the purpose described.

4. In a machine for manufacturing conical tubes from tapering strips the combination with mandrels of different diameters, of a slide carrying said mandrels, means for axially moving said mandrels, means for moving said slide at right angles to the movement of the mandrels, checks for holding said strips, said checks consisting each of two parts between which the edges of the strips are clamped, and means for automatically tightening the said parts of the checks, substantially as and for the purpose described.

5. In a machine for manufacturing conical tubes from tapering strips the combination with mandrels of different diameters, of a slide carrying said mandrels, means for axially moving said mandrels, means for moving said slide at right angles to the movement of the mandrels, checks for holding said strips, means for automatically drawing said strips through the checks, substantially as and for the purpose described.

6. In a machine for manufacturing conical tubes from tapering strips the combination with mandrels of different diameters, of a slide carrying said mandrels, means for axially moving said mandrels, means for moving said slide at right angles to the movement of the mandrels, checks for holding said strips, means for automatically approaching said checks, substantially as and for the purpose described.

7. In a machine for manufacturing conical tubes from tapering strips the combination with mandrels of different diameters, of a slide carrying said mandrels, means for axially moving said mandrels, means for moving said slide at right angles to the movement of the mandrels, means for holding said strips, means for automatically drawing said strips through the checks, and a rack connected with said means and acting upon a pinion operating a right and left hand screw by means of which the two slides carrying the checks are moved toward or away from each other, substantially as and for the purpose described.

698,172. PHOTOGRAPHIC SHUTTER. GAIL BUSHMAN, New Haven, Conn., assignor to E. & H. T. Anthony & Co., New York, N. Y., a Corporation of New York. Filed Apr. 8, 1901. Serial No. 68,604. (No model.)

Claim.—1. In a photographic shutter, the combination with a pivoted shutter-leaf, of a shutter-leaf located adjacent to the inner edge thereof, a spring connecting the said leaf with the adjacent end of the shutter-leaf, and push-buttons connected with the opposite ends of the shutter-leaf which operate to shift the draft of the spring to opposite sides of the pivot of the leaf so as to swing the leaf in one direction or the other and set one of the push-buttons.

2. In a photographic shutter, the combination with a shutter-leaf, of a shutter-leaf located adjacent to the inner edge thereof, a spring having its outer end connected with the shutter-leaf, and its inner end connected with the adjacent end of the shutter-leaf, and push-buttons connected with the opposite ends of the shutter-leaf and standing at right angles to a line passing through the longitudinal axis of the shutter when the same is in its intermediate or semi-opening position, through the pivot of the shutter-leaf and through the inner opening in the shutter-leaf.

3. In a photographic shutter, the combination with a shutter-leaf, of means for operating the same for instantaneous exposures, a swinging time-exposure stop located adjacent to the outer edge of the said leaf, and means for carrying the said stop and moving it into the path of the said edge of the leaf for engagement therewith in making time exposures.

4. In a photographic shutter, the combination with a pivoted shutter-leaf, of means for operating the same for instantaneous exposures, a swinging time-exposure stop located adjacent to the outer edge of the said leaf, and having a central opening, means located in the said opening for limiting the swinging movement of the said stop, and means for carrying the said stop and moving it into and out of the path of the said shutter-leaf.

5. In a photographic shutter, the combination with a pivoted shutter-leaf, of means for operating the same for instantaneous exposures, a swinging time-exposure stop located adjacent to the outer edge of the said leaf, and a time-exposure lever having the said stop pivotally attached to its inner end and having its outer end projected through the camera-box, the said stop being moved into or out of the path of the outer edge of the shutter by means of the said time-exposure lever.

6. In a photographic shutter, the combination with a shutter-leaf, of means for operating the same for instantaneous exposures, a swinging time-exposure stop located adjacent to the outer edge of the shutter, and formed with a tongue extending with the said edge of the shutter, and also formed with a central opening, means entering the said opening for limiting the movement of the stop in either direction, and a time-exposure lever to which the stop is pivotally attached, and by which the stop is brought into or out of the path of the edge of the leaf the movement of which in either direction it stops, according to the way in which its tongue is engaged with the leaf.

698,173. CAMERA. GAIL BUSHMAN, New Haven, Conn., assignor to E. & H. T. Anthony & Co., New York, N. Y., a Corporation of New York. Filed Apr. 9, 1901. Serial No. 68,605. (No model.)

Claim.—1. In a film-carrier, the combination with a centrally-arranged body, of a film-support applied to the front of the said body, a top plate secured to the top of the said body and projecting at its ends beyond the same, journals mounted in the projecting ends of the said plate for connection with the upper ends of the sprockets, sliding journal-carrying plates corresponding to the projecting ends of the top plate and having sliding connection through their inner ends with the lower portion of the said body, and springs connecting the said sliding plates with the body for maintaining the plates in their normal or speed-supporting position.

2. In a film-carrier, the combination with a centrally-arranged hollow body, of a film-support applied to the front thereof, a top plate secured to the top of said body and projecting at its ends beyond the same, journals mounted in the projecting ends of the said top plate for connection with the upper ends of the sprockets, and two sliding journal-carrying plates corresponding to the projecting ends of the top plate and having yielding sliding connection with the lower end of the body.

3. In a film-carrier for cameras, the combination with a body, of journals for the upper ends of the sprockets, and two sliding journal-carrying plates having arms entering recesses in the body and guiding the sliding movement of the plates, and springs connected with the said arms for maintaining the plates in their normal speed-supporting position.

4. In a film-carrier, the combination with a body formed with recesses and spring-chambers, of a top plate secured to the upper end of the said body and carrying journals for the upper ends of the sprockets, sliding journal-carrying plates formed with arms adapted to enter the said recesses, and springs located in the said spring-chambers and connected with the body and with the said arms, and maintaining the said plates in their normal speed-supporting position.

5. In a film-carrier, the combination with a centrally-arranged flanged body, of a film-support applied to the front thereof, a top plate secured to the top of the said body and projecting at its ends beyond the same and beyond the ends of the film-support, a guide-strip located at the lower edge of the film-support and projecting beyond the ends thereof, anti-friction rollers mounted in the forward corners of the top plate and in the ends of the said guide-strip and located adjacent to the ends of the film-support, journals mounted in the projecting ends of the said top plate

for connection with the upper ends of the spokes, and journals connected with the lower portion of the said body for receiving the lower ends of the spokes.

6. In a film-carrier, the combination with a box provided at its rear end with a hinged door, of a rotary bay permanently mounted in the said door and having a stem projecting beyond the inner face thereof, and a film-carrier adapted to be introduced into the camera-box and removed therefrom through the said door and provided with a journal for the take-up spool, the said journal being formed with a socket which receives the said stem of the bay when the door of the camera is closed, whereby the closing of the said door connects the bay with the said spool and the opening of the said door disconnects the bay from the said spool.

7. In a camera, the combination with a combined guiding and light-enclosing trough secured to the inner face of the rear end of the camera-box, of a film-carrier, the body of which is formed with grooves for receiving the forwardly-projecting flanges of the said guiding and light-enclosing trough, whereby the film-carrier is guided in being introduced into and removed from the box, and whereby light is excluded from the box.

698,174. FLUID-CLEANER. DAVID BUTY, Louisville, Ky. Filed July 26, 1901. Serial No. 78,104. (No model.)

Claim.—1. A fluid-cleaning device comprising in combination, an upwardly-curved discharge nozzle or pipe having one of its ends adapted to be temporarily secured within the end of the line, a steam-nozzle located within the discharge end of the pipe and adapted to create a partial vacuum at the end of the line, a rod passing through the wall of said tube and of a length greater than that of the line to be cleaned, and a rotatable sealing-wheel mounted on said rod and having vanes adapted to be revolved by the current of air induced through the line, substantially as specified.

2. A fluid-cleaning device, comprising a curved discharge-pipe having an annular end adapted to fit within the end of the line and a nozzle-shaped discharge end, a steam-supply pipe, a discharge-nozzle communicating therewith and situated within the discharge-pipe, a counterbalancing-weight connected to said steam-pipe, a shaft or axle 14 extending through the casing of the discharge-pipe into the line to be cleaned, a pair of vanes wheel mounted on said axle and adapted to be revolved by a current of air passing through the tube and tapering guiding-plates clamped to said axle on opposite sides of the pair of vanes, substantially as specified.

698,175. RAILWAY-CROSSING. WILLIAM H. COOPER, Knoxville, Tenn., assignor to Oscar R. Galloway, Port Worth, Tex. Filed Feb. 17, 1902. Serial No. 94,697. (No model.)

Claim.—1. A crossing for railways comprising a yielding plate flush with the ends of rails abutting thereagainst and having elevated portions or ribs thereon for forming continuations of the rails.

2. A railway-crossing comprising a yielding plate flush with the ends of rails abutting thereagainst and having ribs thereon for forming continuations for rails and a suitable foundation for said yielding plate.

3. A railway-crossing comprising a yielding plate flush with the ends of rails abutting thereagainst and a bed-casting forming a foundation for said plate and a support for the ends of said rails.

4. A railway-crossing comprising a bed-plate having elevated portions or ribs thereon for forming continuations for rails abutting thereagainst, a bed-casting having a cavity therein for said bed-plate, a plurality of spiral springs between said bed-plate and said bed-casting, and bolts running through said springs and through said bed-casting and said bed-plate for securing said plate in said casting.

5. A railway-crossing comprising a yielding plate flush with the ends of rails abutting thereagainst and a bed-casting having a cavity therein for said bed-plate and forming a foundation therefor and forming a support for rails abutting against said plate.

6. A railway-crossing comprising a yielding plate flush with the ends of rails abutting thereagainst and having elevated portions or ribs for forming continuations for said rails, a bed-casting having a cavity therein for said bed-plate and constituting a foundation therefor, and a stone foundation for said bed-casting.

7. A railway-crossing comprising a yielding plate having continuations for rails abutting thereagainst, a bed-casting having a cavity therein for said plate, and a stone or cement foundation for said bed-casting, said bed-casting having holes therethrough for draining water out of the crossing and said foundation having grooves for conducting the water away from said holes.

8. A railway-crossing comprising a yielding plate having continuations thereon for rails abutting thereagainst and a bed-casting having a cavity therein for said plate and having grooves therein for rails abutting against said plate.

9. A railway-crossing comprising a yielding plate having continuations thereon for rails abutting thereagainst, a bed-casting having a cavity therein for said plate and having grooves therein for rails abutting against said plate, a stone or cement foundation for said bed-casting, and means for securing said bed-casting to said foundation.

698,176. RIDE BEARING FOR RAILWAY CARS. FREDERICK R. GOSWELL, St. Louis, Mo., assignor to Chicago Railway Equipment Company, Chicago, Ill., a Corporation of Illinois. Filed Feb. 23, 1902. Serial No. 94,698. (No model.)

Claim.—1. In a ride bearing for cars, the combination with supports formed with endless grooves in their inner faces, and an endless chain of rollers whose axles are received in said grooves, whereby said rollers are supported wholly by their axles; substantially as described.

2. In a ride bearing for cars, the combination with walls formed with endless grooves in their inner faces, of an endless chain of rollers formed with axles of smaller diameter than the body portion of the rollers, said axles being received in said grooves for supporting the rollers in position, whereby the circumferential speed of the rollers exceeds their horizontal displacement; substantially as described.

3. In a ride bearing for cars, the combination with a casting formed with upwardly-extending walls having grooves in their inner faces, of an

endless chain of rollers whose axles are received in said grooves, said axles wholly supporting the rollers in position, and removable plates which form the top walls of the upper portion of said grooves; substantially as described.

698,177. FINGER. WILLIAM H. CRAFT, Salisbury, N. H. Filed Oct. 21, 1901. Serial No. 78,698. (No model.)

Claim.—1. A portable fence made up of sections having end posts of angle-iron and hooks secured to the end post of one section and engaging the end post of the next adjacent section, each of said hooks having an overhanging portion adjacent to the outer edge of the flange of the post it engages, and a heel adjacent to the angle of the post it engages, substantially as described.

2. A portable fence made up of sections having end posts of angle-iron, and hooks secured to the end post of one section and engaging the end post of the next adjacent section, each of said hooks having an overhanging portion disposed adjacent to the outer edge of the flange of the post carrying it, and a heel adjacent to the angle of said post, substantially as described.

3. A portable fence made up of sections having end posts of angle-iron, and hooks secured to one of the end posts of each section and engaging the end post of the next adjacent section, said hooks having overhanging portions adjacent to the edges of the flanges of adjacent posts and heels adjacent to the angles of said adjacent posts, substantially as described.

4. A portable fence made up of sections having end posts of angle-iron, a corner-post of angle-iron, and hooks for securing the end flanges of the adjacent end sections to the flanges of the corner-post, substantially as described.

5. A portable fence made up of sections having end posts of angle-iron, a corner-post of angle-iron, and hooks secured to the end posts of the adjacent end sections and engaging the corner-post, said hooks having overhanging portions adjacent to the angles of the posts carrying them, and heels adjacent to the angle of the corner-post, substantially as described.

698,178. DRAFT ATTACHMENT FOR DOUBLETRENS. JOHN DAVIS, Piquette, Ohio. Filed Aug. 20, 1901. Serial No. 73,867. (No model.)

Claim.—1. In an improved draft attachment for connecting the doubletrens to the doubletrens, the frame having an open apartment provided with flanges, and formed at its forward and rear ends with a slot; the draw-bar provided with an eye or ring, and formed with the bearing-shoulders; the coil-spring adapted to rest around said draw-bar, and in said open apartment; the circular bearing-plate or washer, formed with a raised portion or collar adapted to fit inside of and support said spring, and also formed with a cavity or recess; and a retaining-pin; all substantially as and for the purpose described.

2. The combination is an improved draft attachment for connecting the doubletrens to the doubletrens; of the rectangular frame having straps for "hooking" the ends of the doubletrens, the rear one being provided with the strap-chain eye, an open apartment formed by said frame and provided with flanges and formed at its forward and rear ends with a slot, the forward slot being much larger than rear slot, so as to permit of any lateral play; the draw-bar adapted to rest in the slot in said frame, and formed with the eye or ring having shoulders adapted to bear against said frame, also the coiled portion provided with a pin-opening; the coil-spring adapted to bear against said flanges and rest around said draw-bar in said open apartment; the circular bearing-plate or washer having the inclined slot for the draw-bar, and formed with the raised portion or collar adapted to fit in said spring, and also provided with a cavity or recess; and the retaining-pin adapted to pass through the opening in said draw-bar and rest in said cavity or recess in said collar; all substantially as and for the purpose described.

698,179. RAIL-ROAD. FRED H. DARRIS and HERMAN W. WYMAN, Worcester, Mass., assignors to American Steel & Wire Company, Worcester, Mass., a Corporation of New Jersey. Filed Dec. 18, 1901. Serial No. 87,512. (No model.)

Claim.—1. A rail-head, comprising two copper terminals or ends, each having a recess in its top or outer surface, and wire strands forming the body portion and extending in said recess, and secured therein by pressure, substantially as shown and described.

2. A rail-head, comprising a body portion, and terminals or ends having their heads roughened, or provided with a series of projections or extensions, and recesses or depressions, substantially as shown and described.

3. A rail-head, comprising a body portion, and terminals or ends having their heads studded with projections, substantially as shown and described.

4. A rail-head, comprising two terminals or ends, each having a recess in its head or outer surface, and wire strands forming the body portion and extending in said recess, and the head or exposed surface of the terminals and of the wire strands, where they extend in the recess in the terminals, roughened, or studded with projections, substantially as shown and described.

698,180. RAIL-ROAD. JOHN T. DEVERE, Greenville, W. Va., assignor of two-thirds to HARRIS L. MORRISON, Greenville, W. Va., and JOHN C. MORRISON and THOMAS R. BULLINGTON, Charleston, W. Va. Filed Jan. 2, 1902. Serial No. 89,948. (No model.)

Claim.—1. The combination, with the end portions of two rails, a fish-plate, and connecting-bolts; of a tapering sleeve split on one side and provided with a projecting flange at its larger end, said sleeve being inserted in one of the bolt-holes and clamped upon one of the said bolts by the pressure of the said fish-plate, and a conductor secured in the said projecting flange, substantially as set forth.

2. The combination, with the end portions of two rails, a fish-plate, and connecting-bolts; of a pair of tapering sleeves each split upon one side and provided with a projecting flange at its larger end, said sleeves being inserted in the bolt-holes and clamped upon the said bolts by the pressure of the said fish-plate, and a conductor coupling the flanges of the said pair of sleeves, substantially as set forth.

3. The combination, with the end portions of two rails, a fish-plate, and connecting-bolts; of a pair of oval and tapering sleeves each split upon one side where narrowest and provided with a projecting flange at its larger end, said sleeves being inserted in the bolt-holes and clamped upon the said bolts by the pressure of the said fish-plate, and a conductor coupling the flanges of the said pair of sleeves, substantially as set forth.

698,181. MUYLS-BRAKE. ALPHRED DUNN, Port Arger, Pa., assignor of one-third to LOUISIANA W. MORRIS, Charleston, Pa. Filed Dec. 4, 1901. Serial No. 81,120. (No model.)

Claim.—1. The combination is a back-pulling brake, of a rear-wheel hub having an internal braking-surface, a fixed polygonal shaft, a

non-rotatable brake-block mounted on said shaft, means for adjusting said brake-block longitudinally of the shaft, a cam-faced collar for moving said brake-block into operative position, a sprocket-wheel, and two concentrically-disposed clutching devices arranged in the same vertical plane, said clutches being interposed respectively between the cam-faced collar and the sprocket-wheel and between the rear-wheel hub and the sprocket-wheel, and adapted for operation in opposite direction.

2. The combination in a back-pedaling brake, of the hub having an inner braking-surface, a polygonal shaft rigidly secured to the frame of the machine, a non-rotatable brake-block mounted for longitudinal movement thereon, a collar adjustably secured in one end of the block and having an end cam, a second cam-faced collar adapted to coast therewith and having a clutch-face, a clutch-ring arranged concentrically with said end collar and carried by the hub, and a sprocket-wheel adapted to be engaged by one of said clutch-faces when traveling in a forward direction, and by the other of said clutch-faces when traveling in a reverse direction, said clutch-faces and the sprocket-wheel teeth being arranged in the same vertical plane, substantially as specified.

3. The combination in a back-pedaling brake, of a rear-wheel hub having an abruptly-terminating internal friction-surface, a longitudinally-movable brake-block adapted to engage said friction-surface, the smaller end of said brake-block being extended slightly beyond the smaller end of the hub friction-surface when the friction-surface of the brake-block and hub are in contact, thereby to avoid uneven wear, a rigid shaft carrying said brake-block, and means for effecting a longitudinal movement of said brake-block, substantially as specified.

4. The combination in a back-pedaling brake, of the rear-wheel hub having an inner braking-surface, a polygonal shaft, a collar having a circular periphery and provided with a central opening conforming to the shaft, an arm secured to or forming part of the collar and adapted to be secured to a fixed portion of the frame of the machine, a brake-block mounted on the shaft and longitudinally movable thereon, a cam-faced collar adjustably secured to said brake-block, a second cam-faced collar revolvable on the shaft-locking collar and provided with a peripheral clutch-face, a ring secured to or formed integral with the hub and also having a peripheral clutch-face, and a sprocket-wheel having an annular groove in its inner face for the reception of said ring, said sprocket-wheel being adapted to engage with either of said clutch-faces, substantially as specified.

5. The combination in a back-pedaling brake, of the hub having an inner braking-surface, a shaft, a non-rotatable brake-block longitudinally movable thereon, a shaft-locking collar having an outer flange, an arm secured to the collar and engaging a fixed portion of the frame of the machine, a cam-faced collar mounted on said locking-collar and provided with a peripheral clutch-face, a ring carried by the hub and also having a peripheral clutch-face, a sprocket-wheel having an annular groove for the reception of said ring and confined in position by the flange of the locking-collar, said sprocket-wheel being adapted to engage with one of said clutch-faces when traveling in a forward direction, and with the opposite clutch-face when traveling in reverse direction, substantially as specified.

6. The combination in a back-pedaling brake, of a shaft of square or polygonal form in cross-section, a disk secured to said shaft and having a peripheral ball-race, a hub also having a ball-race, bearing-balls for the support of the hub, the inner face of said hub being provided with a braking-surface, a brake-block longitudinally movable on the shaft, a compression-spring normally holding said brake-block in inoperative position, a cam-faced collar adjustably secured in the larger end of the brake-block, a shaft-locking collar having a circular periphery and provided with an enlarged annular end flange, an arm projecting laterally from the flange and having ears for securing the same to a fixed portion of the bicycle-frame, a cam-faced collar mounted on the shaft-locking collar and adapted to coast with the cam-collar of the brake-block, there being on the periphery of said second cam-faced collar, a clutching-face, a bearing-ring secured to or formed integral with the hub, a ball-bearing disposed be-

tween said ring and the second cam-faced collar, the peripheral surface of said ring being provided with a clutching-face, and a sprocket-wheel having in its inner face an annular groove for the reception of said ring, and confined in position by the enlarged annular flange of the shaft-locking collar, substantially as specified.

698,182. HOPPER-BOTTOM FOR MIXERS OR THE LIKE. CUMMINGS T. BRADY, Chicago, Ill. Filed June 7, 1901. Serial No. 68,887. (No model.)

Claim.—1. In a hopper, the combination with the sides thereof, of a tilting bottom comprising a plurality of parallel sections concentrically journaled in and extending through the opposite sides of the hopper, a crank secured to each of said sections outside of the hopper, and means for simultaneously swinging said sections into and out of alignment, substantially as described.

2. In a hopper, the combination with the sides thereof, of a tilting bottom comprising a plurality of parallel sections, rods journaled in the opposite sides of the hopper to which said sections are concentrically secured, a crank on an end of each of the said rods, and means connected to the cranks on said rods for simultaneously swinging all of the sections in the same direction into and out of alignment, substantially as described.

3. In combination with a hopper or receptacle and suitable supports therefor, a tilting bottom comprising a plurality of parallel sections concentrically pivoted in the sides of the receptacle, wear-plates on the inner side of the walls of the receptacle through which the pivots of the sections extend, a crank secured to each of said sections outside of the hopper, and means for simultaneously swinging said sections into and out of alignment.

4. In combination with a hopper or receptacle and suitable supports therefor, a tilting bottom comprising a plurality of parallel sections adapted to normally occupy a horizontal plane, a pivot-rod for an end of each section, a crank on each pivot-rod, means in communication with all of the cranks for simultaneously swinging in the same direction all of the sections into and out of alignment, and a stop for limiting the movement of the said means, substantially as described.

5. In combination with a hopper or receptacle and suitable supports therefor, a tilting bottom comprising a plurality of parallel sections, pivots for said sections, a crank extending outwardly from each section, a shifting rod pivoted to all of the cranks, a pivoted operating-rod, having a slot therein, and a projection fixed to said shifting rod and slidably engaging the slot in the operating-rod.

6. In combination with a hopper or receptacle and suitable supports therefor, a tilting bottom comprising a series of pivoted parallel sections adapted to normally occupy a horizontal plane, a crank on each section, a shifting rod connected to all of the cranks, a pivoted operating-lever connected to the shifting rod, means for limiting successive movement of the operating-rod and a catch adapted to engage one of the cranks to lock the operating-lever in normal position, substantially as described.

7. In a hopper, the combination with the sides thereof, of a tilting bottom comprising a series of concentrically-pivoted parallel sections, a crank on each section outside of the hopper, a pivoted operating-lever, means connecting said lever to the crank on each section, and a latching device pivoted to the operating-lever for retaining the same in position through engagement with one of said sections to maintain the sections in alignment, substantially as described.

698,183. APPARATUS FOR REFINING, AGING, BLENDEDING, AND PURIFYING ALCOHOLIC LIQUORS. JAMES F. DUFFY, Chicago, Ill. Filed Sept. 20, 1901. Serial No. 71,008. (No model.)

Claim.—1. In an apparatus of the class described, the combination with a supply-tank, of a heating-tank arranged at a lower level, an air-compressor, a supply-pipe leading from the supply-tank to the heating-

tant, a pipe leading from the air-compressor to the supply-pipe and entering the same at an acute angle in the direction of flow in said supply-pipe, a coil within the heating-tank connected with the supply-tank, means for heating the interior of said heating-tank, an atomizing-tank, an atomizer therein connected with the heating-tank and means for ejecting a current of impregnated air upon the liquor as it emerges from the atomizer, substantially as described.

2. In an apparatus of the class described, the combination with an atomizing-tank, of an atomizer therein provided with means for supplying it with a flow of mingled air and liquor and a nozzle directed toward the spray of the atomizer and provided with means for supplying it with a flow of air impregnated with a volatile substance, substantially as described.

3. In an apparatus of the class described, the combination with an atomizing-tank, of an atomizer therein, a heating-tank, a supply-tank and air-compressor, connecting-pipes leading the liquor from the supply-tank, injecting air into the same, passing in the form of a coil through the heating-tank and leading to the atomizer, means for heating the interior of said heating-tank, a heated receptacle containing a volatile reagent, an air-pipe supplying air to said heated receptacle and a pipe leading therefrom and discharging into the spray of the atomizer, substantially as described.

4. In an apparatus of the class described, the combination of a supply-tank, a heating-tank at a lower level and connected therewith by a suitable connection, an air-injector in said connection, an air-compressor, connected in said injector and adapted to inject a current of air into the liquor, a heated coil within the heating-tank joined to the connection with the supply-tank, a suitable atomizing-tank, an atomizer therein connected with said coil, a heated receptacle containing a volatile reagent, a connection between said receptacle and the atomizing-tank, means for forcing compressed air into said heated receptacle, suitable distilling apparatus and connections between said atomizing-tank and said distilling apparatus, substantially as described.

698,184. METHOD OF REFINING, AGING, BLENDEDING, AND PURIFYING ALCOHOLIC LIQUORS. JAMES F. DUFFY, Chicago, Ill. Filed Sept. 20, 1901. Serial No. 71,009. (No specimens.)

Claim.—1. In a process for the treating of liquors, the following steps in the order mentioned, to wit: the mingling therewith of air under pressure, the heating of the mixture, the addition thereto of a volatile reagent and the distillation of the products, substantially as described.

2. In a process for the treating of liquors, the following steps: first, the mingling with the liquor, of air under pressure; second, the heating of the mixture; third, the standing of the heated mixture; fourth, the impregnating of air with a volatile reagent, and fifth, the mingling of the impregnated air with the atomized heated mixture, substantially as described.

3. In a process for the treating of liquors, first, the mingling with said liquor, of air under pressure; second, the heating of the mixture thus formed; third, the standing of the heated mixture; fourth, the impregnating of air with a volatile reagent; fifth, the mingling of the impreg-

nated air and the atomized mixture; sixth, the distilling of the product, substantially as described.

4. In a process for the treating of liquors, the standing of the liquor and the mingling of a volatile reagent with said liquor, while the latter are in the form of a spray, substantially as described.

698,185. CABLE-SUSPENDING HANGER. RALPH DE PUECO, Cleveland, Ohio, assignor of one-half to WILLIAM T. BORTON, Sr., Cleveland, Ohio. Filed Mar. 18, 1902. Serial No. 98,488. (No model.)

Claim.—1. A cable-suspending hanger comprising a piece of sheet metal which is bent into the shape required to form two hooks which are arranged, at the top and bottom, respectively, of the hanger, and having the following: a lower hook *d* arranged mouth up and forming a bearing for the cable or cables to be suspended by the hanger and formed entirely by the sheet-metal piece and having the dimensions required to render it capable of being bent completely around and thereby controlling the said cable or cables, and an upper hook *c* arranged mouth down and formed by a cross-forming piece of wire embraced by an end portion of the sheet-metal piece, substantially as and for the purpose set forth.

2. A cable-suspending hanger comprising a piece of sheet metal which is bent into the shape required to form two hooks which are arranged at the top and bottom, respectively, of the hanger, and having the following: a lower hook *d* arranged mouth up and forming a bearing for the cable or cables to be suspended by the hanger and formed entirely by the sheet-metal piece and having the dimensions required to render it capable of being bent completely around and thereby controlling the said cable or cables, and an upper hook *c* arranged mouth down and formed by a cross-forming piece of wire embraced by an end portion of the sheet-metal piece and extending beyond the said end portion of the sheet-metal piece at the free end of the said upper hook, substantially as and for the purpose set forth.

3. A cable-suspending hanger having the following: an upper hook *c* arranged mouth down, a lower hook *d* arranged mouth up and formed entirely by a sheet-metal piece which is plate and long enough to render it capable of being bent completely around and thereby controlling the cable or cables to be suspended by the hanger, and a web *f* joining the two hooks together and widest at its end which is contiguous to the lower hook and at the said end extending laterally beyond opposite sides of the

upper hook, and the free end of the lower hook being slotted longitudinally from the free extremity of the said hook inwardly so as to form two arms which are long enough to render them capable of straddling opposite ends, respectively, of the abovedescribed portion of the web when the said hook, upon the application of the hanger, is bent around and thereby caused to completely enclose the abovesaid cable or cables, substantially as and for the purpose set forth.

4. A cable-suspending hanger having the following: an upper hook arranged mouth down, a lower hook arranged mouth up and formed entirely by a sheet-metal piece which is pliable and long enough to render it capable of being completely bent around and thereby enclosing the cable or cables to be suspended by the hanger, and an upright web joining the two hooks together and widest at its lower end and at the said end extending laterally beyond opposite sides of the upper hook, and the free end of the lower hook being slotted centrally and longitudinally from the free extremity of the said hook inwardly so as to form two arms which are long enough to render them capable of straddling opposite ends, respectively, of the abovesaid lower and wider portion of the web when the said hook, upon the application of the hanger, is bent around and thereby caused to completely enclose the abovesaid cable or cables, substantially as and for the purpose set forth.

5. The combination, with a supporting-cable, and a cable or cables to be suspended from the supporting-cable, of a hanger comprising the following: an upper portion hung upon the supporting-cable and formed by a sheet-metal piece, a web joining the upper and lower portions of the hanger together and widest at its lower end and at the said end extending laterally beyond opposite sides of the upper portion of the hanger, and the abovesaid lower portion of the hanger being slotted to form two arms which straddle opposite ends, respectively, of the abovesaid wider portion of the web, substantially as and for the purpose set forth.

6. The combination, with a supporting-cable, and a cable or cables to be suspended from the supporting-cable, of a hanger comprising the following: an upper portion hung upon the supporting-cable, a lower portion affording bearing to the suspended cable or cables and formed entirely by a sheet-metal piece, a web joining the upper and lower portions of the hanger together and widest at its lower end and at the said end extending laterally beyond opposite sides of the upper portion of the hanger, and the abovesaid lower portion of the hanger being slotted to form two arms which straddle opposite ends, respectively, of the abovesaid wider portion of the web, substantially as and for the purpose set forth.

7. The combination, with a supporting-cable, and a cable or cables to be suspended from the supporting-cable, of a hanger comprising the following: an upper portion hung upon the supporting-cable, a lower portion affording bearing to the suspended cable or cables and formed entirely by a sheet-metal piece, an upright web joining the said upper and lower portions of the hanger together and widest at its lower end and at the said end extending laterally beyond opposite sides of the upper portion of the hanger, and the abovesaid lower portion of the hanger being slotted centrally and longitudinally to form two arms which straddle opposite ends, respectively, of the abovesaid lower and wider portion of the web and are bent over and closely against both sides of the web, substantially as and for the purpose set forth.

8. The combination, with a supporting-cable, and a cable or cables to be suspended from the supporting-cable, of a hanger comprising the following: an upper portion hung upon the supporting-cable, a lower portion affording bearing to the suspended cable or cables, a web between the said portions of the hanger and widest at its lower end and at the said end extending laterally beyond opposite sides of the upper portion of the hanger, and the abovesaid lower portion of the hanger having two arms which straddle opposite ends, respectively, of the abovesaid lower and wider portion of the web and are bent over and closely against both sides of the said end portion of the web, substantially as and for the purpose set forth.

698,186. WIRE-FENCE MACHINE. JOHN W. DWIGGINS and LAURENCE SWANK, Anderson, Ind., assignors to the Dwiggins Wire Fence Company, Anderson, Ind., a Corporation of Indiana. Filed Oct. 24, 1901. Serial No. 70,048. (No model.)

Claim.—1. In a wire-fence machine, the combination of means for feeding a series of running-wires therethrough, means for distributing a stay-wire transversely of the series of running-wires with single portions of the stay-wire adjacent and substantially parallel with the running-wires, and means for attaching the said portions of the stay-wire to the running-wires.

2. In a wire-fence machine, the combination of means for feeding a series of running-wires therethrough, means for distributing a stay-wire transversely of the series of running-wires with single portions of the stay-wire adjacent and substantially parallel with the running-wires, and means for twisting said parallel portions of the stay-wire about the adjacent running-wires.

3. In a wire-fence machine, the combination of means for intermittently feeding a series of running-wires therethrough, means for distributing a stay-wire transversely of the series of running-wires with single portions of the stay-wire adjacent and substantially parallel with the running-wires, and means for attaching said portions of the stay-wire to the running-wires.

4. In a wire-fence machine, the combination of means for intermittently feeding a series of running-wires therethrough, means for distributing a stay-wire transversely of the series of running-wires with single portions of the stay-wire adjacent and substantially parallel with the running-wires, and means for twisting said substantially parallel portions of the stay-wire about the adjacent running-wires.

5. In a wire-fence machine, the combination of means for feeding a series of running-wires therethrough, means for arranging a stay-wire transversely of the running-wires, the stay-wire having single portions substantially parallel with and adjacent the running-wires, and means for twisting said substantially parallel portions of the stay-wire about the running-wires.

6. In a wire-fence machine, the combination of means for feeding a series of running-wires therethrough, means for arranging a stay-wire transversely of the running-wires, the stay-wire having single portions substantially parallel with and adjacent the running-wires, and means for attaching said substantially parallel portions of the stay-wire to the running-wires.

7. In a wire-fence machine, the combination of means for feeding a series of running-wires therethrough, means for distributing a substantially endless stay-wire transversely of the running-wires with single portions of the stay-wire adjacent and substantially parallel with the running-wires, means for cutting the said wire to the desired length, means for clamping the ends of the stay-wire so formed, and means for twisting the substantially parallel portions of the stay-wire about the adjacent running-wires.

8. In a wire-fence machine, the combination of means for feeding a series of running-wires therethrough, of means for distributing a substantially endless stay-wire transversely of the running-wires with single portions of the stay-wire adjacent and substantially parallel with the running-wires, means for cutting the said wire to the desired length, means for clamping the ends of the stay-wire so formed, and means for moving the substantially parallel portions of the stay-wire to the running-wires.

9. In a wire-fence machine, the combination of means for feeding a series of wires therethrough, of a needle-carriage, means for reciprocating said carriage transversely of the running-wires, a needle carried by said carriage and adapted to carry a stay-wire, means for reciprocating said needle transversely of the line of movement of the carriage during

such movement whereby a substantially endless stay-wire may be distributed by said needle transversely of the running-wires with portions thereof adjacent and substantially parallel with the running-wires, means for cutting the distributed portion of the stay-wire to the desired length, means for clamping the ends of the several portions of the stay-wire, and means for twisting the substantially parallel portions of the stay-wire about the adjacent running-wires.

10. In a wire-fence machine, the combination of a stay-wire-receiving table, means for feeding a series of running-wires across said table, a series of pins arranged adjacent the running-wires and projecting above the table, means for distributing a stay-wire around the said pins and transversely of the running-wires whereby portions of the stay-wire will be adjacent and substantially parallel with the running-wires, means for engaging and twisting said substantially parallel portions of the stay-wire about the running-wires, and means for withdrawing the pins from the stay-wire.

11. In a wire-fence machine, the combination with means for feeding a series of running-wires therethrough, of a needle-carriage, means for reciprocating said carriage transversely across the series of running-wires, a swinging needle journaled in said carriage so as to swing in a plane substantially parallel with the line of running-wires and adapted to receive a stay-wire, and means for swinging said needle during the movement of the carriage, whereby a stay-wire may be distributed in a zigzag line transversely of the running-wires.

12. In a wire-fence machine, the combination with means for feeding a series of running-wires therethrough, of a needle-carriage, means for reciprocating said carriage transversely across the series of running-wires, a swinging needle journaled in said carriage so as to swing in a plane substantially parallel with the series of running-wires and adapted to receive a stay-wire, a pair of oppositely-arranged cranks carried by the needle-shaft, and two groups of cams each group of cams being arranged to engage one only of the cranks whereby each crank and its set of cams will operate to reciprocate the needle during the travel of the carriage in one direction.

13. In a wire-fence machine, the combination with means for feeding a series of running-wires therethrough, a needle-carriage, means for reciprocating said carriage transversely across the series of running-wires, a swinging needle journaled in said carriage so as to swing in a plane substantially parallel with the running-wires and adapted to receive a stay-wire, a pair of oppositely-arranged cranks carried by the needle-shaft in the line of the carriage, and two groups of cams each adapted to engage and throw one of the cranks, the arrangement of cams being such that only the trailing crank will operate to oscillate the needle during either direction of travel of the carriage.

14. In a wire-fence machine, the combination with means for feeding a series of running-wires therethrough, of means for laying a stay-wire adjacent the running-wires, a series of twisting-gears, means for normally withdrawing said twisting-gears out of the line of movement of the running-wires, means for projecting said twisting-gears into engagement with the running-wires and stay-wire, and means for rotating said gears after their projection.

15. In a wire-fence machine, the combination with means for feeding a series of running-wires therethrough, of a stay-wire-distributing needle, and means for reciprocating said needle both transversely and longitudinally with relation to the running-wires.

16. In a wire-fence machine, the combination with means for feeding a series of running-wires therethrough, of a stay-wire-distributing needle, and means for moving said needle adjacent the running-wires both transversely and longitudinally.

17. In a wire-fence machine, the combination of a stay-wire-distributing needle, means for reciprocating the same across the running-wires, means for cutting the stay-wire, means for clamping the ends of said stay-wire, and means for reversing the direction of the free end of the stay-wire supply before it returns the clamping means.

18. In a wire-fence machine, the combination of a stay-wire-distributing needle, means for reciprocating the needle across the running-wires, means for cutting the stay-wire, means for clamping the ends thereof, a trip-lever 22, a finger 26 carried thereby, a pawl carried by the needle and adapted to deflect the trip-lever during the movement of said needle in one direction, and means for returning the trip-lever to its initial position, the arrangement being such that the finger 26 will be brought into engagement with the free end of the stay-wire supply and reverse its direction for a reversal of motion of the needle.

19. In a wire-fence machine, the combination of a stay-wire-distributing needle, means for reciprocating said needle across the running-wires, means for cutting the stay-wire, means for clamping the ends thereof, a trip-lever 22, a finger 26 carried thereby, a pawl carried by the needle and adapted to deflect the trip-lever during the movement of said needle in one direction, and means for returning the trip-lever to its initial position, the arrangement being such that the finger 26 will be brought into engagement with the free end of the stay-wire supply and reverse its direction for a reversal of motion of the needle.

20. In a wire-fence machine, means for positively clamping each running-wire and feeding uniform lengths thereof therethrough, whereby

all the running-wires of a given length of completed fencing will be of uniform length.

21. In a wire-fence machine, a feeding-drum for the running-wires, consisting in part of means for positively clamping each running-wire at successive points and moving the same through a uniform distance.

22. In a wire-fence machine, a feeding-drum consisting of a series of heads each adapted to receive one of the running-wires, means carried by each head for clamping and twisting its running-wire, and means for simultaneously advancing all of said heads through a uniform peripheral distance.

23. In a wire-fence machine, a feed-head adapted to receive a running-wire, a series of lugs projecting from the periphery thereof, a series of levers arranged to cooperate with said lugs, means for rotating said head, and means for swinging each lever toward and from its lug, whereby a running-wire may be automatically clamped and twisted between the lugs and levers, uniformly fed through the machine, and released from the feeder, substantially as shown and described.

24. In a wire-fence machine, a feeding-drum for the running-wires, consisting of a series of heads, one for each running-wire, means for adjusting the effective diameter of each of said heads, means carried by each of said heads for positively clamping its running-wire, and means for rotating the entire drum, whereby uniform lengths of all running-wires will be fed through the machine independent of the relative size of said wires.

25. In a wire-fence machine, a feeding-drum for the running-wires, consisting of a series of connected heads, one for each running-wire, a series of lugs projecting from the periphery of each head, a series of levers carried by each head and arranged one adjacent each lug, means for swinging each lever into and away from juxtaposition with its lug so as to clamp the running-wire and twist it transversely, a series of fingers projecting from the periphery of each drum, means for adjusting said fingers toward and from the periphery so as to vary the effective diameter of each head, and means for rotating the head, substantially as and for the purpose set forth.

26. In a wire-fence machine, the combination with wire feeding and guiding mechanism, of twisting mechanism consisting of a plurality of dotted twisting-gears, a rack meshing with all of said gears, means for projecting said gears intermittently into the twisting position, and means for giving the rack a half-rotation for each projection of the twisting-gears into twisting position.

27. In a wire-fence machine, the combination with wire feeding and guiding mechanism, of twisting mechanism consisting of a plurality of dotted twisting-gears, means for projecting said gears intermittently into twisting position, and means for rotating said gears.

28. In a wire-fence machine, the combination with wire feeding and guiding mechanism, of twisting mechanism consisting of a plurality of dotted twisting-gears, means for projecting said gears intermittently into twisting position, and means for rotating said gears in opposite directions for alternate projections of said gears into twisting position.

29. In a wire-fence machine, the combination of a stay-wire-receiving table, means for feeding a series of running-wires across said table, a series of stay-wire pins projected above said table, a stay-wire-distributing needle, means for moving said needle both transversely and longitudinally of the running-wires so as to distribute the stay-wire around the stay-wire pins and transversely of the running-wires with portions adjacent and substantially parallel with the running-wires, a series of sliding guards mounted adjacent some of the stay-wire pins and each carrying a pin adapted to lie normally adjacent a stay-wire pin and above the position to be occupied by the distributed stay-wire, the arrangement being such that the needle operates to retract the guard-pin from its normal position at the time of the distribution of the stay-wire around the adjacent stay-wire pin.

30. In a wire-fence machine, the combination with means for feeding a plurality of running-wires therethrough, of means for attaching thereto a transverse stay-wire having portions adjacent and substantially parallel with the running-wires, each means consisting of a plurality of twisting-gears, means for causing said gears to engage the running-wires and stay-wire so as to twist the substantially parallel portions of the stay-wire about the running-wires, and guards arranged to engage the stay-wire adjacent the running-wires and regulate the length of the twist.

31. In a wire-fence machine, the combination with means for feeding a plurality of running-wires therethrough, a plurality of twisting-gears, means for causing said gears to engage the running-wires and those portions of a transverse stay-wire which lie adjacent and substantially parallel to the running-wires so as to twist such portions around the running-wires, a guide for each running-wire, a plurality of fingers, and means for moving said fingers into opposition to the guides so as to engage the stay-wire and regulate the length of twist upon the running-wires.

32. In a wire-fence machine, the combination with a stay-wire-receiving table, of means for feeding a plurality of running-wires across said table, a plurality of stay-wire pins projecting above said table, adjacent

the running-wires, a plurality of guides one for each running-wire, a plurality of fingers, means for bringing said fingers adjacent the running-wires each in opposition to one of the guides, twisting mechanism adapted to engage portions of a stay-wire and wrap them upon the running-wires, and means for withdrawing the stay-wire pins, substantially as described.

33. In a wire-fence machine, the combination with a stay-wire-receiving table, of means for feeding a plurality of running-wires across said table, a plurality of stay-wire pins projecting above said table adjacent the running-wires, a plurality of guides one for each running-wire, each adjustable longitudinally of its wire, a plurality of adjustable fingers, means for bringing said fingers adjacent the running-wires each in opposition to one of the guides, twisting mechanism adapted to engage portions of a stay-wire and wrap them upon the running-wires, and means for withdrawing the stay-wire pins, substantially as described.

34. In a wire-fence machine, the combination of a stay-wire-distributing needle, means for reciprocating the needle across the running-wires, means for cutting the stay-wire, means for clamping the ends of the stay-wire, and means for engaging the fresh end of the stay-wire supply and reversing the direction thereof before it releases the clamping means.

35. In a wire-fence machine, the combination with a stay-wire-applying means, of means for positively clamping each running-wire after the stay-wire has been applied, and means for moving said clamping means whereby all of the running-wires of a given length of completed fencing will be of uniform length.

36. In a wire-fence machine, the combination with a stay-wire-applying means, of means for positively engaging and kinking each running-wire after the stay-wires have been applied, and means for moving said clamping and kinking means to feed the running-wires through the machine.

37. In a wire-fence machine, the combination with means for applying stay-wires, means for positively clamping the running-wires after the stay-wires have been applied, and means for intermittently moving said clamping means whereby uniform lengths of running-wires are intermittently drawn through the machine.

698,187. INSECT-DESTROYING MACHINE. CHARLES V. DYER and WILLIAM S. WILLIAMS, CORP., INC. Filed Aug. 26, 1901. Serial No. 73,305. (No model.)

Claim.—1. In a machine of the character described, in combination, a box, a revolving brush, an arched axle to open a row of plants, a wheel upon the outer end thereof, and a head adapted to gather the plants to the brush.

2. In a machine of the character described, in combination, a vertically-adjustable box, a laterally-adjustable revolving brush, and a head adapted to gather plants to the brush.

3. In a machine of the character described, in combination, a box, a supporting-runner thereunder, means to adjust the box vertically upon the runner, a laterally-adjustable frame supported on the box, and a revolving brush mounted in the frame.

4. In a machine of the character described, in combination, a box, a supporting-runner thereunder, means to adjust the box vertically relative to the runner, a laterally-adjustable frame supported on the box, a revolving brush mounted in the frame, a head adapted to gather the plants for the brush, an arched axle adapted to open a row of plants and a wheel upon the outer end of the axle.

698,188. AUTOMOBILE MOWING-MACHINE. GEORGE E. BLAIR and JOHN F. STURGEON, CHICAGO, ILL. Filed Jan. 11, 1901. Serial No. 42,385. (No model.)

Claim.—1. In a mowing or other machine adapted to perform work

while being self-propelled over the ground, a rotatable shaft, as J, connecting mechanism adapted to operate the parts required to perform the said work while passing over the ground, said shaft connected to the traction-wheel by gearing adapted to permit the traction-wheel to operate independently when either is under restraint caused by the steering mechanism, a motor for said shaft, and means between the motor and shaft to cause the driving action of the motor upon said shaft to be either forward or backward, all combined with the steering mechanism substantially as described.

2. In a mowing or other machine adapted to perform work while being self-propelled over the ground, a rotatable shaft, as J, connecting mechanism adapted to operate the parts required to perform the said work while passing over the ground, said shaft connected to the traction-wheel by differential gearing adapted to permit the traction-wheel to operate independently when either is under restraint caused by the steering mechanism, motor for said shaft, and means between the motor and shaft to cause the driving action of the motor upon the shaft to be forward or backward, all combined with the steering mechanism substantially as described.

3. In a mowing or other machine adapted to perform work while being self-propelled over the ground, a rotatable shaft, as J, connecting mechanism adapted to operate the parts required to perform the said work while passing over the ground, said shaft connected to the traction-wheel by differential mechanism, and a clatching mechanism interposed between the said shaft J and the differential mechanism whereby the propelling force may be disconnected from the traction-wheel, all combined substantially as described.

4. In a mowing or other machine adapted to perform work while being self-propelled over the ground, a rotatable shaft, as J, said shaft connected by suitable gearing to the traction-wheel and also adapted, by suitable connecting mechanism, to perform work while so traveling over the ground, the combination therewith of a motor suitably geared to said shaft whereby the motive power of said motor, through the instrumentality of said shaft, is transmitted, in part to the traction-wheel and in part to that portion of the mowing-machine adapted to perform the labor required while passing over the ground, the said mechanism for transmitting motion from the motor to the said shaft consisting essentially of means for converting the single action of the motor into either a forward or backward drive, substantially as described.

5. In a mowing or other machine adapted to perform work while being self-propelled over the ground, a rotatable shaft, as J, said shaft connected by suitable gearing to the traction-wheel and also adapted, by suitable connecting mechanism, to perform work while so traveling over the ground, the combination therewith of a motor suitably geared to said shaft whereby the motive power of said motor, through the instrumentality of said shaft, is transmitted, in part to the traction-wheel and in part to that portion of the mowing-machine adapted to perform the labor

required while passing over the ground, the said mechanism for transmitting motion from the motor to the said shaft consisting essentially of a reversibly-acting clatching mechanism, said clatching mechanism consisting of a gear on the motor-shaft, a shaft, as G, suitably geared to the shaft from which power is distributed to various working parts of the machine, said having the loosely-moving gears F and F' thereon, and the friction-clutches G' and G'' for locking either of the said gears to the said shaft at will, substantially as described.

6. In an automobile moving or other machine main supporting and traction wheels, framework for the working parts carried thereon, a supplemental supporting wheel, or wheels, as D, a shaft connecting the parts in which said wheels are supported, said shaft forming at the same time the bed of the engine and fuel-reservoir, substantially as described.

7. In an automobile moving or other machine main supporting and traction wheels, framework for the working parts carried thereon, a supplemental supporting wheel, or wheels, as D, a shaft connecting the parts in which said wheels are supported, said shaft consisting of a tube forming an oil-reservoir and exhaust chamber, or chamber, and ending during the ends of the tube and constituting the ends of the exhaust-chamber, substantially as described.

8. In an automobile moving or other machine main supporting and traction wheels, framework for the working parts carried thereon, a supplemental supporting wheel, or wheels, as D, a shaft connecting the parts in which said wheels are supported, said shaft consisting of a tube forming an oil-reservoir and exhaust chamber, or chamber, and ending during the ends of the tube and constituting the ends of the exhaust-chamber, substantially as described.

9. In a moving or other machine adapted to perform work while being self-propelled over the ground, the combination of the main supporting and traction wheels, a framework for the working parts carried thereon, a supplemental supporting wheel or wheels, a shaft connecting the parts, said shaft during the ends of the tube and constituting the connection between the tube and the parts in which the wheels are supported, and driving-partitions in said tube forming a fuel-reservoir and exhaust-chamber, said tube also constituting the bed of the engine.

10. In a moving or other machine adapted to perform work while being self-propelled over the ground, the combination of a shaft, as J, having a gear connection with the traction-wheel, an engine for driving the shaft J, a reversing-gear in the train of gears between the engine and the traction-wheel, a lever controlling said reversing-gear, a guiding-wheel, and a connection between said wheel and the lever whereby the latter may also control the wheel.

11. In a moving or other machine adapted to perform work while being self-propelled over the ground, the combination of a shaft, as J, having a gear connection with the traction-wheel, an engine for driving the shaft J, a reversing-gear between the engine-shaft and the shaft J, an oscillating lever controlling said reversing-gear, a guiding-wheel, a gear K having a wrist-pin connected by rod K' with the guiding-wheel, and a plain P on the reversing-lever in mesh with the gear K, whereby the oscillation of the lever controls the reversing-gear, and the axial rotation of the lever controls the guiding-wheel.

12. In a moving-machine adapted to perform work while being self-propelled over the ground, the combination with a one-way engine, the outer crank-shaft, a reversing-gear connection between said shaft and the engine, and a driving-gear connection between the shaft and the traction-wheel.

13. In a moving-machine adapted to perform work while being self-propelled over the ground, the combination with a one-way engine, the outer crank-shaft, a reversing-gear connection between said shaft and the engine, a counter-shaft in rear of the axle, a bevel-wheel gearing with a plain on the rear end of the crank-shaft and having a spur-plain P' right thereon, a driving-gear P' operated by said plain, bevel-wheels U, V, connected respectively to the two traction-wheels, and links U', V', connecting the bevel-wheels to the driving-gear.

14. In a moving-machine adapted to perform work while being self-propelled over the ground, the combination of the cutting apparatus, the outer crank-shaft, an engine, having a gear connection with a driving-plain J on the front end of the shaft, and a wheel J' on the rear end of the shaft for communicating power from the shaft.

15. In a moving-machine adapted to perform work while being self-propelled over the ground, the combination of the main frame having a tongue-crank, an axle and traction-wheel carried by said frame, an engine-bed fitting in said crank at its rear end, a supporting-wheel for the front end of the bed, and gearing between the engine and traction-wheel.

698,189. MACHINE FOR DRILLING INVERT-HOLES IN METAL. LEO WHEEL-FILLER, CHICAGO, ILL. Filed May 29, 1901. Serial No. 41,147. (No model.)

Claim.—1. The combination of a frame formed with a circular series of correspondingly-curved guiding-slides, drills journaled in bearings

in said slide, shafts journaled at one end in said bearings and geared to the drills, a circular series of individually-rotatable bearings mounted on the frame outside of the circular series of slides, the shafts being also journaled in said latter bearings, an arm projecting from each of the individually-rotatable bearings, and links connecting the arms of adjacent bearings throughout the circular series, whereby all of said bearings and the shafts journaled therein may be adjusted simultaneously, substantially as shown and described.

2. The combination of a circular series of drills, a corresponding series of shafts disposed at right angles to the drills, the shafts being geared at their inner ends to the drills, a circular series of bearings for the outer ends of said shafts, and means for axially moving said bearings simultaneously for the purpose of so moving said shafts as to either increase or diminish the diameter of the circle of said drills, substantially as shown and described.

3. The combination of a circular series of drills, a corresponding series of shafts extending at right angles to the drills, said shafts being geared at their inner ends to the drills, bearings common to said shafts and drills for constantly maintaining them in proper relation, a circular series of rotatable bearings for the outer ends of said shafts, and means for axially turning said rotatable bearings, substantially as shown and described.

4. The combination of a circular series of drills, a corresponding series of shafts extending at right angles thereto, the drills being geared to the inner end of said shafts and adjustable therewith, a circular series of bearings for the outer ends of the shafts, an arm projecting from each of said bearings, and links connecting all of said arms, whereby all of the bearings may be turned on their axes uniformly for the purpose of increasing or diminishing the diameter of the circle of said drills through the medium of said shafts, substantially as shown and described.

5. The combination of a circular series of radially-adjustable drills, actuating mechanism for each drill having permanent operative engagement therewith, a circular series of individually-rotating supports—one for each of said actuating mechanism, whereby the latter and the drills are adapted to swing in a common plane, and means for turning all said supports simultaneously, substantially as shown and described.

6. The combination of a series of horizontally-swinging drills, the centers upon which the drills swing being arranged in a circle, and adjusting mechanism common to the swinging centers of all the drills, substantially as shown and described.

7. The combination of a frame formed with a circular series of correspondingly-curved slides, bearings fitting the slides and adjustable therein, drills mounted in the bearings, and mechanism for radially adjusting all of said bearings, simultaneously, substantially as shown and described.

8. The combination of vertically-disposed drills, a vertically-fixed horizontally-movable carriage beneath the drills, and work-supports on the carriage and vertically adjustable independently of each other, whereby work on one support may be raised and operated upon independently of the other support, substantially as shown and described.

698,190. FINE-FUEL FURNACE. WILLIAM H. FISHER, Chicago, Ill. Filed June 4, 1902. Serial No. 18,861. (No model.)

Claim.—1. The combination with a fine-fuel furnace, of means for supplying thereto in suspension and in rapid succession measured charges of air and fuel combined, substantially as described.

2. The combination with a fine-fuel furnace, of means for supplying thereto in suspension successive charges of air and fuel combined, said means comprising a chamber between the furnace and the source of fuel supply, within which chamber the air and fuel are combined, substantially as described.

3. The combination with a fine-fuel furnace of means for supplying thereto air and fuel in successive measured charges, said means being adjustable so as to vary the quantity of air and fuel contained in each charge, substantially as described.

4. The combination with a fine-fuel furnace, of a series of valves for supplying fuel supply pipes, a series of valves for supplying air supply pipes, each of said valves connecting their respective sources of supply with the furnace, and means for causing the supply-pipes of each series to operate successively and intermittently, substantially as described.

5. In a fine-fuel furnace, the combination with a combustion chamber, of means for feeding the blasts of fine fuel upwardly to a zone of combustion therein and in rapid succession, substantially as described.

6. The combination with a fine-fuel furnace, a fuel-hopper and an air-chest, of series of valves for supplying fuel and air to the furnace through said series of pipes simultaneously or successively but intermittently, substantially as described.

7. The combination with a hermetically-sealed fine-fuel furnace provided with a tortuous combustion-chamber and a contracted discharge-opening, of means for supplying a mixture of air and fuel to said furnace in a series of jets operating successively or simultaneously but intermittently, substantially as described.

8. The combination with a hermetically-sealed fine-fuel furnace, having a tortuous combustion-chamber and a contracted discharge-opening, of series of valves for fuel supply pipes connected at intervals with said furnace, the valves in said pipes being adapted to operate successively or alternately but intermittently, substantially as described.

9. The combination with a hermetically-sealed fine-fuel furnace having a tortuous combustion-chamber and a contracted discharge-opening, of an air-chest and a fuel-hopper respectively connected with the furnace at intervals, the supply of air and fuel being simultaneous through each connection, and all said connections operating simultaneously or successively but intermittently, substantially as described.

10. In a fine-fuel furnace, means for supplying a fluid fuel element thereto, said means comprising a series of pipes connecting said furnace with a source of supply, and a corresponding series of successively and intermittently operating valves for controlling the admission of said fluid fuel element to said pipes from said source of supply, substantially as described.

11. In a fine-fuel furnace, means for supplying a fluid fuel element thereto, said means comprising a series of pipes connecting said furnace with a source of supply, and a corresponding series of intermittently-operating valves for controlling the admission of said fluid fuel element from said source of supply to said pipes, said valves being arranged to operate either simultaneously or successively, all substantially as described.

12. The combination with a fine-fuel furnace, of a fuel and air feeding mechanism comprising a fine-fuel hopper, a series of pipes connecting the same with the furnace, a corresponding series of feed-chambers, a corresponding series of adjustable intermittently-operating valves controlling ports connecting said chambers with the hopper and with the pipes, a slide-valve for simultaneously controlling the ports leading from the hopper to the feed-chambers, and means for supplying air in measured charges to the feed-pipes, substantially as described.

13. The combination with a fine-fuel furnace, of a fuel and air feeding mechanism comprising a fine-fuel hopper, a series of pipes connecting the same with the furnace, a corresponding series of feed-chambers, a corresponding series of adjustable intermittently-operating valves controlling ports connecting said chambers with the hopper and with the pipes, a slide-valve for simultaneously controlling the ports leading from the hopper to the feed-chambers, an air-chest, a series of pipes corresponding in number with the fuel-pipes and connecting said chest with the furnace, and a series of adjustable intermittently-operating valves located in said chest and controlling the discharge-ports leading therefrom to the air-pipes, substantially as described.

14. The combination with a fine-fuel furnace, of a fuel and air feeding mechanism comprising a fine-fuel hopper, a series of pipes connecting the same with the furnace, a corresponding series of feed-chambers, a corresponding series of adjustable valves controlling ports connecting said chambers with the hopper and with the pipes, a slide-valve for simultaneously controlling the ports leading from the hopper to the feed-chambers, an air-chest, a series of pipes corresponding in number with the fuel-pipes and connecting said chest with the furnace, a series of adjustable valves located in said chest and controlling the discharge-ports leading therefrom to the air-pipes, and a slide-valve for controlling the ports leading from the air-chest to the air-pipes, substantially as described.

15. The combination with a fine-fuel furnace, of a fuel and air feeding mechanism comprising a fine-fuel hopper, a series of pipes connecting the same with the furnace, a corresponding series of feed-chambers, a corresponding series of adjustable valves controlling ports connecting said chambers with the hopper and with the pipes, a slide-valve for simultaneously controlling the ports leading from the hopper to the feed-chambers, an air-chest, a series of pipes corresponding in number with the fuel-pipes and connecting said chest with the furnace, a series of adjustable valves located in said chest and controlling the discharge-ports leading therefrom to the air-pipes, a slide-valve for controlling the ports leading from the air-chest to the air-pipes, and a gear connection between the series of fuel-valves and the series of air-valves, substantially as described.

16. In a fine-fuel furnace, the combination with a combustion-chamber, of means for supplying intermittent rapidly-ascending and upwardly-directed blasts of fine fuel to a zone of combustion therein, substantially as described.

17. In a fine-fuel furnace, the combination with a combustion-chamber, of a plurality of tuyeres therein, and means for supplying rapidly-ascending intermittent and upwardly-directed blasts of fine fuel in suspension alternately through adjacent tuyeres to a zone of combustion in said combustion-chamber, substantially as described.

18. In a fine-fuel furnace, the combination with a combustion-chamber, of a tuyere arranged adjacent to the bottom thereof to direct blasts of fuel in an upward direction to a zone of combustion in said combustion-chamber, and means for supplying rapidly-ascending intermittent blasts of fine fuel in suspension, through said tuyere to said zone of combustion, substantially as described.

698,191. FINE-FUEL COMBUSTION. WILLIAM H. FISHER, Chicago, Ill. Filed July 31, 1901. Serial No. 78,347. (No specimen.)

Claim.—1. The process of burning fine fuel which comprises measuring a charge of fine fuel and a charge of a fluid fuel element and in forcing said measured charges simultaneously and in suspension upward into a zone of combustion, substantially as described.

2. The process of combustion which comprises supplying a zone of combustion with rapidly-ascending fuel charges in suspension, each charge consisting of a measured quantity of fine fuel and a correspondingly measured and proportioned quantity of a fluid fuel element, substantially as described.

3. The process of combustion which comprises supplying a zone of combustion within a closed combustion-chamber, with measured and relatively proportioned quantities of fine fuel and of fluid fuel element in suspension in rapidly-ascending interrupted blasts, substantially as described.

4. The process of combustion which comprises supplying a zone of combustion within a closed combustion-chamber with successive measured charges of fine fuel and a fluid fuel element in suspension and combined in relatively proportioned quantities, substantially as described.

5. The process of combustion which comprises the introduction into a supply-pipe of a measured charge of fine fuel, together with a measured and correspondingly-proportioned charge of fluid fuel element, and in then supplying said combination of fine fuel and fluid fuel element in suspension from said supply-pipe to a zone of combustion in a closed combustion-chamber in interrupted blasts, substantially as described.

6. The process of combustion which comprises supplying a zone of combustion in a closed combustion-chamber with measured charges of fine fuel, and measured and correspondingly-proportioned charges of fluid fuel element and in intimately intermixing said fuel elements, and the gases within said combustion-chamber by means of interrupted and conflicting blasts, substantially as described.

7. The process of combustion which comprises the combustion of fine fuel in suspension within a combustion-chamber and the introduction into said combustion-chamber, during the process of combustion, of interrupted and interfering blasts, substantially as described for the purposes described.

8. The process of combustion which comprises supplying fine fuel to a zone of combustion within a combustion-chamber and promoting the combustion of said fine fuel in suspension, and the intermixture of the combustible gases and other fuel elements within said combustion-chamber, by the introduction into said chamber of interrupted and interfering blasts, substantially as described.

9. The process of combustion which comprises the combustion of fine fuel in suspension, in a closed combustion-chamber, and the production within said combustion-chamber, during the process of combustion, of an agitating and mixing action by the introduction into said combustion-chamber of interrupting and interfering blasts, substantially as described for the purposes described.

10. The process of combustion which comprises the introduction of fine fuel to a zone of combustion and the promotion of the intimate intermixture of said fine fuel, in suspension, with a fluid fuel element by the use of upwardly-directed, interrupted blasts, substantially as described.

11. The process of combustion which comprises the introduction of fine fuel to a zone of combustion and the promotion of the intimate intermixture of said fine fuel in suspension with a fluid fuel element by means of upwardly-directed and alternately-acting interrupted blasts, substantially as described.

698,192. WHISTLE-CLIP. WILLIAM FISHER, Pittsburgh, Pa. Assignor of one-half to Andrew Fisher, Pittsburgh, Pa. Filed Nov. 24, 1901. Serial No. 62,600. (No model.)

Claim.—A whistle-clip, comprising two members hinged together at their rear ends and having interlocking portions at their front ends to

form a link, and a bolt for securing the interlocking ends together, said bolt being in the rear of the bearing-surfaces of the eye, substantially as set forth.

698,193. BELL-TUBE CLEANER. WILLIAM H. FISHER and John T. Hall, Pittsburgh, Pa. Assignors to the Union Bell-Tube Cleaner Company, Pittsburgh, Pa., a Corporation of Pennsylvania. Filed Jan. 17, 1902. Serial No. 700,622. (No model.)

Claim.—1. In mechanism of the class described, the combination of the transverse bar or rail, means for vertically adjusting the same, the laterally-adjustable slide carried by said bar or rail, the bracket having the cylindrical downward extension and the upward extension, the clamp upon said slide engaging said downward extension, the outer rotary drive journal in said bracket, the inner concentric endwise-removable drive rotatably connected to said first-named drive, means for causing said inner drive from endwise movement, the feed-rod engaging said inner drive, the rotary engine carried by said bracket, the shaft of said engine, having a journal-bearing in said upward extension, and carrying a gear-wheel meshing with the gear-wheel upon said outer drive, substantially as specified.

2. In mechanism of the class described, the combination of the transverse bar or rail, means for vertically adjusting the same, the laterally-adjustable slide carried by said bar or rail, the bracket upon said slide, having a transversely split cylindrical bearing, and the endwise-removable enlargement connecting the rotation of said bearing, the rotary drive journal at opposite ends thereof in said bearing, the gear-wheel mounted centrally of said drive in the space separating the sections of said bearing and partly locked by said enlargement, the feed-rod engaging said inner drive, the rotary engine carried by said bracket, the shaft of said engine carrying a gear-wheel meshing with said first-named gear-wheel, and the guard-strip secured at one end thereof to the upper portion of said enlargement, curved around the gear-wheel upon the engine-shaft, thence partly around the gear-wheel upon said drive, and covered to the lower portion of said enlargement, substantially as specified.

3. In mechanism of the class described, a transverse bar or rail, a laterally-adjustable slide mounted upon said bar or rail, a bracket upon said slide, and having a cylindrical downward extension at one end portion thereof, clamped to said slide and rotatable therein to allow said bracket to be turned, a rotary drive having bearings in the opposite end portion of said bracket, the intermediate portion of said bracket resting and turning upon the upper surface of said slide, a feed-rod actuated by said drive, and a rotary engine mounted upon said bracket, and geared to said drive, substantially as specified.

4. In mechanism of the class described, a transverse bar or rail, a laterally-adjustable slide carried by said bar or rail, a bracket upon said slide having a bearing at one end portion thereof, an outer rotary drive

Journal in said bearing, an inner endwise-removable sleeve rotatably engaged by said first-mentioned sleeve, a clamp upon said bracket and engaging the outer end of said inner sleeve, a feed-rod actuated by said inner sleeve, and a rotary engine carried by said bracket, and geared to said outer sleeve, substantially as specified.

698,194. BREAKDOWN GUN. WILLIAM E. GATE, Worcester, Mass., assignor to himself and Benjamin P. Greene, Worcester, Mass. Filed Apr. 6, 1902. Serial No. 11,783. (No model.)

Claim.—1. In a breakdown gun, the combination of the gun-frame, a barrel having a lag pivoted in the gun-frame, and an ejector mechanism comprising a spring-pressed ejector-belt, an operating-lever pivoted in the barrel-lag in front of the hinge-pin to engage the gun-frame at the rear of the pivot of said lever when the gun is opened, a pusher actuated by the lever to impart a positive motion to the ejector-belt, and a detent for the ejector-belt arranged to be released by the pusher, substantially as described.

2. In a breakdown gun, the combination of the gun-frame, a barrel having a barrel-lag fitting therein, a hinge-pin pivotedly connecting said parts, and an ejector mechanism comprising a spring-pressed ejector-belt, an operating mechanism for the ejector-belt mounted in a longitudinal slot in the barrel-lag, and comprising an operating-lever pivoted in front of the hinge-pin in position to engage the gun-frame at the rear of its pivot when the gun is open, a pivoted swinging piece or pusher, the rear end of the actuating-lever being coacted in said pusher, and a spring-detent, the pusher being arranged to first engage and impart a positive motion to the ejector-belt, and to then release the spring-detent, permitting the ejector-belt to fly back to the end of its travel when the gun is substantially wide opened, substantially as described.

3. In a breakdown gun, the combination of a gun-frame, a barrel pivotedly mounted at the forward end of the gun-frame, locking connections for holding the barrel in its normal position, a trigger controlling the action of the gun, a trigger-spring, and connections for diminishing the tension of the trigger-spring when the gun is unlocked or opened, substantially as described.

4. In a breakdown gun, the combination of a gun-frame, a barrel pivotedly connected to the forward end of the gun-frame, and an action comprising a longitudinally-movable spring-pressed firing-pin, a trigger therefor, a safety-catch mounted at one side of the trigger for locking the same when desired, and a substantially bell-crank-shaped cocking-lever having one leg thereof extending forward to be operated by the barrel-lag, and the other leg thereof engaging and operating both the firing-pin and safety-catch, substantially as described.

5. In a gun, the combination of the gun-frame, a barrel pivotedly mounted at the forward end thereof, a locking-bolt for holding the parts in their normal or closed position, a trigger controlling the action of the gun, a locking-bolt spring engaging one side of a leg on the locking-bolt, and a trigger-spring engaging the opposite side of said leg, substantially as described.

6. In a gun, the combination of the gun-frame, a barrel pivotedly mounted at the forward end thereof, a longitudinally-movable spring-pressed firing-pin mounted in the gun-frame, a trigger having a catch-section for directly engaging the firing-pin, a cocking-lever for forcing back the firing-pin, a locking-bolt for holding the gun in its shot or normal position, a locking-bolt spring engaging one side of a leg on the locking-bolt, and a trigger-spring engaging the opposite side of said leg, said parts being arranged so that the tension of the trigger-spring will be diminished whenever the gun is unlocked or opened, substantially as described.

7. In a shell-extracting mechanism for breakdown guns, the combination of an ejector-belt, a pivoted pusher or starter lever therefor, and connections for actuating the starter-lever when the gun is opened to impart a positive initial motion to the ejector-belt, the upper end of the starter-lever engaging a shoulder at the rear of a recess in the under side of the ejector-belt, so that said starter-lever will always be in position to be moved forward when the gun is closed and cannot engage with or interfere with the ejector-belt spring, substantially as described.

8. In a gun, the combination of a longitudinally-movable spring-pressed firing pin or bolt, a trigger having a catch or detent section for engaging a notch in the firing-pin, and a safety-catch pivoted at one side of the trigger in position to engage a pin or leg in the side thereof, said parts being arranged so that the firing-pin will hold the trigger in its retracted or pulled-back position after the gun is fired, and will prevent said trigger from being thrown forward in position to be engaged by the safety-catch, substantially as described.

698,195. SHEARS. WILLIAM C. KENNEDY, Thawville, Pa., assignor to one-half to Steven P. Cole, Pittsburgh, Pa. Filed July 6, 1901. Renewed Mar. 18, 1902. Serial No. 98,721. (No model.)

Claim.—1. A shears comprising a cutting member having a handle provided with a pivoting-plate and an extension beyond the pivot in the plane of said plate, a blade provided with a recess parallel with the edge thereof to receive said extension and a pivoting-ear adapted to fit upon the outer face of said plate, and a pivot passing through said ear and plate, substantially as specified.

2. A shears comprising opposite cutting members each having a handle portion provided with a pivoting-plate and a beveled extension in the plane thereof, a cutting-blade for each member provided with an undercut recess to receive said extension and a pivoting-ear to fit upon the outer face of said plate, and a pivoting device passing through the ears and plates of both members of the shears to hold the blades against longitudinal movement and to clamp the members of the shears into contact with each other, substantially as specified.

698,196. CULTIVATOR. ROBERT W. HENRY, Germantown, Ind. Filed Oct. 18, 1901. Serial No. 78,575. (No model.)

Claim.—1. In a cultivator, the combination with the draft-frame; of the inverted-U-shaped balls 12 suspended therefrom; devices swivelled on the lower ends of said balls; cultivator-frames loosely coupled to the devices; and loose connections between the cultivator-frames.

2. In a cultivator, the combination with the draft-frame; of the inverted-U-shaped balls suspended therefrom; devices swivelled on the lower ends of said balls; cultivator-frames coupled loosely to the devices; and inverted-U-shaped coupling arches or yokes connecting said cultivator-frames.

3. In a cultivator, the combination with a gang of cultivator-frames; and a draft-frame common thereto; of a plate loosely mounted upon each cultivator-frame; and inverted-U-shaped couplings loosely connecting the adjacent ends of each two plates for lateral and vertical movements.

4. In a cultivator, the combination with a gang of cultivator-frames; and a draft-frame common to all; of a plate mounted upon each cultivator-frame and provided with intermediate and end slots; bolts passed through the intermediate slots; and the arched couplings having their ends loosely connected with the end openings or slots for lateral and vertical movements.

5. In a cultivator comprising a series of gangs, and in combination therewith, a pair of bars loosely connected for vertical and lateral movements to the beams of two adjacent gangs; and means for adjustably connecting the meeting ends of said bars.

6. In a cultivator as described, and in combination therewith, a pair of bars adjustably connected at their outer ends to the two intermediate cultivator-frames and adjustably connected at their inner ends to each other; and arches loosely connecting the two outer cultivator-frames in series.

7. In a cultivator, the combination with the framework, of pairs of gangs or cultivator-frames; draft-balls loosely suspended from the framework and having one of the gangs connected to each of their terminals; arches loosely connecting in series these gangs connected to each ball; and an adjustable connection between the inner gangs of the series.

8. In a cultivator, the combination with the framework; of pairs of gangs or cultivators; opposite adjustable draft-balls loosely suspended from the framework, and having one of the gangs connected to each of their terminals; arches adjustably and loosely connecting in series these gangs connected to each ball; and a pair of adjustably-connected bars loosely connected at their outer ends to the inner gang of said series.

698,197. ADJUSTABLE TROLLEY-SUPPORTER. THOMAS R. STURDY and EDWARD HILL, Indianapolis, Ind. Filed July 6, 1901. Serial No. 61,690. (No model.)

Claim.—1. The combination with a railroad-track and an electrically-propelled vehicle on said track, of a current-conductor situated on one side and above the plane of said track, a current-conveyor and an extendible arm pivotedly mounted on the top of said vehicle, said extendible arm extending outwardly and horizontally therefrom to support the said current-conveyor and maintain the same in contact with the conductor, and means for extending said arm.

2. The combination with a railroad-track and an electrically-propelled vehicle on said track, of a current-conductor situated at one side of and above the plane of the track, a telescoping arm pivotedly mounted on the top of said vehicle, and a current-conveyor mounted on the free end of said arm.

3. The combination with a railroad-track and an electrically-propelled vehicle on said track, of a current-conductor situated at one side of and above the plane of said track, a telescoping arm pivotedly mounted on the top of said vehicle, a current-conveyor mounted on the free end of said arm and means for locking said telescoping arm in a fixed position.

4. The combination with an electrically-propelled vehicle of a horizontally-extending swinging extendible arm, a current-conveyor mounted on the free end of said arm, and means situated at one end of the vehicle whereby the position of the said swinging-arm may be changed and whereby said arm may be locked in position.

5. The combination with an electrically-propelled vehicle and a current-conveyor, of a horizontally-extending swinging extendible arm pivotedly mounted on the top of said vehicle, and independent means for swinging said arm and for actuating or telescoping the same.

6. The combination with an electrically-propelled vehicle and a current-conveyor, of a horizontally-extending swinging extendible arm pivotedly mounted on the top of said vehicle, an extendible arm telescoping in said sleeve, and independent means for rotating said sleeve in a horizontal plane and for extending said telescoping arm.

7. The combination with an electrically-propelled vehicle and a current-conveyor, of a horizontally-extending sleeve pivotedly mounted on the top of said vehicle, an extendible arm telescoping in said sleeve, and independent means for rotating said sleeve in a horizontal plane and for extending said telescoping arm.

8. The combination with an electrically-propelled vehicle and a current-conveyor, of a sleeve-supporting table pivotedly mounted on the top of said vehicle, a horizontally-extending sleeve secured on said pivotal table, an extendible arm telescoping in said sleeve, and a pivot on the free end of said arm wherein said current-conveyor is pivoted, and independent means for rotating said supporting-table and for extending said telescoping arm.

9. The combination with an electrically-propelled vehicle and a current-conveyor, of a sleeve-supporting table, a depending central pivotal stem integral on said table and having a central vertical bore, a horizontally-extending sleeve secured on said table, an extendible arm telescoping into said sleeve, a rack on the side of said extendible arm, a vertically-extending shaft adapted to turn in the central bore of said stem, a pinion on the upper end of said shaft, a rack-pinion adapted to engage said rack and said shaft-pinion simultaneously, and means for rotating said table and for operating said central shaft, substantially as set forth.

698,198. TROUSERS-SUPPORTER. GEORGE E. HILL, Scranton, Pa. Filed Sept. 11, 1901. Serial No. 78,800. (No model.)

Claim.—1. A trousers-supporter consisting of two thin hard plates of suitable material shaped to conform to the anatomy of a person at the hips so as to fit snugly and rest thereon, said plates being applied to the inside of a pair of trousers at about the waist-line, substantially as described.

2. A trousers-supporter consisting of two thin hard plates of suitable material curved to conform to the anatomy of a person at the hips so as

to snugly and rest thereon, said plates being removably applied to the inside of a pair of trousers at about the waist-line, substantially as described.

3. The combination with a pair of trousers of a pair of plates applied to the inside thereof at or near the waist-line so that when said trousers are in position on the wearer the plates will rest upon and be supported by the hips, said plates being made of the shape and size to conform to the anatomy of the body at those points, and said plates being provided with hooked projections which extend through the trousers from the inside and project from said trousers as to the inside the upper edge of a belt beneath the same, substantially as described.

4. As a product of manufacture a supporting-plate for a pair of trousers constructed from a single piece of hard material and shaped to conform to the anatomy of a person at the hips, the said plate being thickened on its lower edge and provided with means for attaching it to the inside of a pair of trousers, substantially as described.

5. As a product of manufacture, a supporting-plate for a pair of trousers constructed from a single piece of this hard material, and shaped to conform to the anatomy of a person at the hips, the said plate being thickened at its lower edge and covered on its face which extends next to the inner surface of a pair of trousers when applied thereto, substantially as described.

6. As a new article of manufacture, a supporting-plate for a pair of trousers, constructed from a single piece of this hard material and shaped to conform substantially to the anatomy of a person at the hips, the said plate being thickened at its forward end and also at its lower edge, substantially as described.

698,199. AUTOMATIC CUT-OFF FOR GAS-SHOVER. EDGAR C. HILLMAN, Newport News, Va. Filed Oct. 27, 1903. Serial No. 34,921. (No model.)

Claim.—1. In a gas-shower, the combination with a valve for controlling the gas-supply, of a hand-operated device for partially opening the valve to burn a taper flame, and a supplemental device connected to said hand-operated device and operating through a lever to open the valve further when a larger flame is required, said supplemental device being adapted to be actuated by placing a vessel on the stove.

2. In a gas-shower, the combination with a valve for controlling the gas-supply, of a hand-operated device for partially opening the valve to burn a taper flame, and a supplemental device connected to said valve to open it further when a larger flame is required, said supplemental device being located normally below the stove-top, and being connected with the hand-operated device so that when the latter is operated to light the taper flame, the supplemental device will be raised above the stove-top in position to be operated by placing a vessel thereon.

3. In a gas-shower, the combination with a valve for controlling the gas-supply, of an automatic device for opening the valve by placing a vessel on the stove, said device being normally out of operative position, and a hand-operated device for setting the automatic device into operative position, said hand-operated device being connected to the supply-valve as to partially open the same before setting the automatic device.

4. In a gas-shower, the combination with a valve for controlling the gas-supply, of a taper-flame device, and a full-flame device, said devices being connected to the supply-valve, and being also connected together, so that the actuation of the taper-flame device will set the full-flame device into operative position.

5. In a gas-shower, the combination with a supply-valve, a device for partially opening the valve by hand to burn a taper flame, and a supplemental device actuated by a vessel placed on the stove to open the valve further when a larger flame is required, said hand device acting to open the valve to a limited extent in the first part of its movement, and the further movement of said device operating to lift the supplemental device into operative position without further opening the valve.

6. In a gas-shower, the combination with a supply-valve, of a device to operate said valve by hand, and an automatic device to open the valve

further by a vessel placed on the stove, said hand device having a preliminary movement to open the valve partially to burn a taper flame, and a connection between the hand device and the automatic device, whereby the continued movement of the hand device after lighting the taper flame lifts the automatic device into operative position without further opening the valve.

7. A valve mechanism for gas-stoves, comprising a reciprocating supply-valve, a casing therefor, an actuator, means co-operating with the actuator and the valve-stem for partially opening the valve, automatic mechanism co-operating with the actuator to further or fully open the valve and means for disengaging said mechanism and said actuator, whereby the valve may be closed independently of said automatic mechanism.

8. A valve mechanism for gas-stoves, comprising a reciprocating valve, a casing therefor, an actuator co-operating with the valve-stem, a cam-rod on said actuator, a rock-lever co-operating with said cam-rod, a rod attached to said lever, and means for rendering inoperative said lever and said cam-rod whereby the valve may be closed and remain closed independently of said rock-lever and its connections.

9. A valve mechanism for gas-stoves, comprising a reciprocating valve, a casing therefor, an actuator, a nut on the valve-stem, co-operating means on said nut and said actuator to partially open the valve, a cam-rod on said actuator, a rock-lever co-operating with said cam-rod, a rod attached to said lever and means for rendering inoperative said lever and said cam-rod, whereby the valve may be closed independently of said lever and its connections.

10. A valve mechanism for gas-stoves, comprising a non-rotary, reciprocating valve, a casing therefor, a cap on said casing co-operating with the valve-stem, cam-rod on said cap, a rocking lever pivoted to said casing, and engaging said cam-rod, a rod attached to said rock-lever, and adapted to be engaged by a handle on the stove-top to further or fully open the valve, and means for rendering inoperative said lever and said cam-rod, whereby the valve may be closed independently of said rock-lever.

11. A valve mechanism for gas-stoves comprising a non-rotary reciprocating valve, a casing therefor, a cap on said casing, a nut secured to the valve-stem, co-operating means on said nut and said cap to partially open the valve, a cam-rod on said cap, a rock-lever pivoted to said casing and engaging said cam-rod, a rod attached to said rock-lever, and adapted to be engaged by a handle on the stove-top to further or fully open the valve and means for rendering inoperative said lever and said cam-rod, whereby the valve may be closed independently of said rock-lever and its connections.

698,200. VOLTMETER-SWITCH. JAMES I. KIRBY, Syracuse, N. Y. Filed Jan. 11, 1903. Serial No. 35,255. (No model.)

Claim.—1. In a voltmeter-switch, the combination with an insulating-base, of a series of contact-terminals arranged thereon in pairs to be connected to the respective lines to be tested, a pair of terminals adapted to be connected to the opposite poles of the voltmeter, an insulating member movably supported on the base, contacts arranged on said member in pairs, connections between the two contacts of each pair, one of each pair being adapted to remain continuously in contact with one voltmeter-terminal, the other adapted to make connection successively with the line-terminals as the insulating member is moved over the base.

2. In a voltmeter-switch, the combination with an insulating-base, of a series of contact-terminals arranged thereon in pairs to be connected to the respective lines to be tested, a pair of terminals adapted to be connected to the opposite poles of the voltmeter, an insulating member journaled on the base, contacts arranged on said member in pairs, connections between the two contacts of each pair, one of each pair being adapted to remain continuously in contact with one voltmeter-terminal, the other adapted to make connection successively with the line-terminals as the insulating member is rotated.

3. In a voltmeter-switch, the combination with a base of insulating material, of two metallic rings thereon adapted to be connected to the opposite poles of the voltmeter, an annular series of terminals thereon arranged in pairs to be connected to the respective lines to be tested, an insulating member journaled on the base, contacts arranged on said member in pairs, and connections between the two contacts of each pair, one of each pair being adapted to remain continuously in contact with one ring, the other adapted to make connection successively with the line-terminals as the insulating member is rotated.

4. In a voltmeter-switch, the combination with a base of insulating material, of two metallic rings arranged concentrically on the rear surface of the base, an annular series of contact-terminals on the base arranged in pairs around the rings, binding-posts connected to said terminals for the attachment of the line-wires, two binding-posts connected to the respective rings for the voltmeter-wires, an insulating member journaled on said base concentrically with the rings, a handle to turn the arm, contact-shells, forming plunger-contacts, arranged in pairs on the ends of said arm, connections between the plunger-contacts of each pair, plungers arranged in said shells and having tips extending outwardly through holes in their bases, and springs arranged in said shells and bearing on the plungers to maintain the tips in contact with the contact-terminals on the base, the outer tips of each pair being adapted to make contact with the contact-terminals of the respective lines as the arm is rotated and the inner tips on each arm being adapted to remain in permanent contact, one with the inner ring, the other with the outer.

5. In a voltmeter-switch, the combination with a base of insulating material, of two metallic rings of different diameters arranged concentrically on the rear surface of the base, two binding-posts connected to the respective rings to receive the wires from the opposite poles of the voltmeter, an annular series of contact-terminals on the base, arranged in pairs around the rings, binding-posts for said contact-terminals to receive the opposite wires of the lines to be tested, an insulating member journaled on the base, contacts arranged on said member in pairs and connections between the two contacts of each pair, one of each pair being adapted to remain continuously in contact with one voltmeter-post, the other adapted to make connection successively with the line-terminals as the insulating member is rotated.

6. In a voltmeter-switch, a base of insulating material, a series of metallic contact-terminals arranged in a ring on the rear face of the base, binding-posts connected to the respective contact-terminals for the line-wires, said terminals and binding-posts being arranged diametrically opposite in pairs, two metallic rings or voltmeter-terminals let into the rear face of the base, flush therewith and arranged concentrically within the ring of contact-terminals, one ring within the other, binding-posts for the voltmeter-wires connected one with each ring, an internally-shouldered sleeve having an integral shoulder to engage with the disk, a tabular Shank engaging with the sleeve, a dial on the outer end of the Shank inscribed with the numbers corresponding to the lines to be tested, a shaft having a threaded lower end extending through said sleeve and Shank, a handle on the inner end of the dial, a pointer on the handle, to indicate numbers on the dial, a rotating arm of insulating material fitted to the inner end of said shaft, four plunger-contacts carried on said arm and arranged in pairs, one pair adjacent to each end of the arm, the contacts of each pair being connected by a line and one of each pair adapted to remain in continuous connection with one voltmeter-post, the other adapted to make connection with the line-terminals as the arm is rotated.

7. In a voltmeter-switch, a disk-shaped base of insulating material, a series of metallic contact-terminals arranged in a ring on the rear face of the base and lying flush therewith, binding-posts connected to said respective contact-points and extending outwardly around the edge of the disk for the line-wires, said terminals and binding-posts being arranged diametrically opposite in pairs and being equal in number to the lines to be tested, two metallic rings or voltmeter-terminals let into the rear face of the base and lying flush therewith and arranged concentrically within the ring of contact-terminals, one ring within the other, binding-posts on the edge of the disk for the voltmeter-wires connected one with each ring, an internally-shouldered sleeve having an integral shoulder to engage with the disk, a tabular Shank engaging with the sleeve, a dial on the outer end of the Shank inscribed with numbers on its outer face corresponding to the lines to be tested, said sleeve and Shank extending through said sleeve and Shank, an integral plate and handle on the outer end of the shaft, a pointer on the plate, one on the inner end of the shaft to secure the parts adjustably in position, a rotating arm of insulating material fitted to the inner end of said shaft and secured thereon by one of the shaft, four plunger-contacts carried on said arm and arranged in pairs, one pair adjacent to each end of the arm, the contacts of each pair being connected by a line and one of each pair adapted to remain in continuous connection with one voltmeter-post, the other adapted to make connection with the line-terminals as the arm is rotated.

8. In a voltmeter-switch, a disk-shaped base of insulating material, a series of metallic contact-terminals arranged in a ring on the rear face of the base and lying flush therewith, binding-posts connected to the respective contact-terminals and extending outwardly around the edge of the disk for the line-wires, said terminals and binding-posts being arranged diametrically opposite in pairs and being equal in number to the lines to be tested, two metallic rings or voltmeter-terminals arranged on the rear face of the base, and concentrically within the circle of contact-terminals, one ring within the other, binding-posts on the edge of the disk for the voltmeter-wires connected one with each ring, an internally-shouldered sleeve having an integral shoulder to engage with the disk, a tabular Shank engaging with the sleeve, a dial on the outer end of the Shank inscribed with numbers on its outer face corresponding to the lines to be tested, a shaft having a threaded lower end extending through said sleeve and Shank, an integral plate and handle on the outer end of the shaft, a pointer on the plate, one on the inner end of the shaft to secure the parts adjustably in position, a rotating arm of insulating material fitted to the inner end of said shaft and secured thereon by the shaft or nut, four plunger-contacts carried on said arm and arranged in pairs, one pair adjacent to each end of the arm, the contacts of each pair being connected by a line and one of each pair adapted to remain in continuous connection with one ring, the other adapted to make connection with the line-terminals as the arm is rotated, said plunger-contacts being composed each of two shells engaging with each other and arranged to extend through the arm forming a pocket, of a plunger arranged in said pocket with its contact-tip extending outwardly through a hole in the bottom of one shell end of a spring engaging with the plunger to force the tip outwardly against the contact-terminals substantially as described and shown.

698,201. FRAME FOR DOOR, WINDOW, &c. JOHN R. WILSON, Pittsburgh, Pa. Filed May 10, 1901. Serial No. 35,355. (No model.)

Claim.—1. The combination of the wall and frame, and a yielding strip located between the same.

2. The combination of the wall and frame, and a yielding strip formed of hair located between the same.

3. The combination of the wall and frame, and a yielding strip formed of cuttle-bone located between the same.

4. The combination of the wall and frame, a yielding strip formed of cuttle-bone adapted to engage with said wall, and a tape on said strip adapted to engage with said frame.

5. The combination of the wall having an opening therein, a frame, a yielding strip formed of cuttle-bone adapted to engage with the inside face of said opening, and a tape secured to said strip and adapted to engage with the inside face of said frame.

6. The combination of the wall having an opening therein, a frame, a yielding strip formed of cuttle-bone located within the space formed by the opening in the wall and frame and adapted to engage with the inside face of said opening, and a tape attached to said strip and adapted to engage with the inside face of said frame.

7. The combination of the wall having an opening therein, a frame, a yielding strip formed of filled cuttle-bone located within the space formed by the opening in the wall and frame and adapted to engage with the inside face of said opening, and a paper tape attached to said strip and adapted to engage with the inside face of said frame.

8. As a new article of manufacture, a strip formed of yielding material adapted for insertion between the stile of a door or window frame and the wall, and a tape secured to one side of said strip.

9. As a new article of manufacture, a yielding strip formed of hair adapted for insertion between the stile of a door or window frame and the wall, and a tape secured to one side of said strip.

10. As a new article of manufacture, a yielding strip formed of cuttle-bone adapted for insertion between the stile of a door or window frame and the wall, and a tape secured to one side of said strip.

11. As a new article of manufacture, a yielding strip formed of filled cuttle-bone adapted for insertion between the stile of a door or window frame and the wall, and a tape secured to one side of said strip.

12. As a new article of manufacture, a strip adapted for insertion between the stile of a door or window frame and the wall formed of a yielding material, and a tape secured to one side of said strip and of less width than the same.

13. As a new article of manufacture, a yielding strip adapted for insertion between the stile of a door or window frame and the wall formed of hair, and a tape secured to one side of said strip and of less width than the same.

14. As a new article of manufacture, a yielding strip adapted for insertion between the stile of a door or window frame and the wall formed of cattle-hair, and a tape secured to one side of said strip and of less width than the same.

15. As a new article of manufacture, a yielding strip adapted for insertion between the stile of a door or window frame and the wall formed of felted cattle-hair, and a tape secured to one side of said strip and of less width than the same.

16. As a new article of manufacture, a yielding strip adapted for insertion between the stile of a door or window frame and the wall formed of felted cattle-hair, and a tape secured to one side of said strip by stitches, said tape being of less width than the strip.

698,202. STRAIN-SUPPLEMENT. JAMES HUGHES, Glasgow, Scotland. Filed Oct. 31, 1901. Serial No. 22,022. (No model.)

Claim.—1. The combination of the combustion-chamber of a steam-boiler, with superheating-pockets projecting from the top of the combustion-chamber up into the steam-space of the boiler, substantially as described.

2. The combination of the combustion-chamber of a steam-boiler with superheating-pockets fitted to the top plates of the combustion-chamber, and open at their lower ends to said combustion-chamber and closed at their upper ends, which project into the steam-space of the boiler.

3. The combination of the combustion-chamber of a steam-boiler with superheating-tubes fitted to the top plates of the combustion-chamber, and projecting at their upper ends into the steam-space, said tubes being closed at their upper ends, but open at their lower ends to the combustion-chamber.

4. The combination of the combustion-chamber of a steam-boiler with superheating-pockets fitted to the top plates of the combustion-chamber and forming grater-stays therefor, substantially as described.

5. The combination of the combustion-chamber of a steam-boiler, with superheating-tubes fitted to the top plates of the combustion-chamber and projecting into the steam-space of the boiler with spacing-pieces between the tubes of a row, as and for the purpose described.

6. The combination of the combustion-chamber of a steam-boiler with superheating-tubes fitted to the top plates of the combustion-chamber, and projecting into the steam-space of the boiler, with spacing-pieces between the tubes of a row and a strap embracing the tubes, substantially as described.

698,208. SWIVEL-LOCK. GEORGE F. HUGHES and JAMES T. GIB, Worcester, Mass., assignors to Crompton & Knowles Lock Works, Worcester, Mass., a Corporation of Massachusetts. Filed Dec. 11, 1901. Serial No. 22,422. (No model.)

Claim.—1. In a swivel-chamber motion, in which the swivel-chamber have a reciprocating motion in a horizontal plane, the combination with a rack, a disk carrying a series of pins extending at right angles from the face thereof to engage a toothed segment or rack on the inner end of a swivel-chamber, and mechanism intermediate the rack and disk, to rotate the disk by the movement of the rack, of said swivel-chamber, having a toothed segment, or rack on its inner end, substantially as shown and described.

2. In a swivel-chamber motion, in which the swivel-chamber have a reciprocating motion in a horizontal plane, the combination with a rack, a disk carrying a series of pins to engage a toothed segment or rack on the inner end of a swivel-chamber, and mechanism intermediate the rack and disk to rotate the disk by the movement of the rack, of said swivel-chamber having a toothed segment or rack on its inner end, comprising two longer and tooth, an intermediate shorter tooth, and two recesses between the teeth, substantially as shown and described.

3. In a swivel-chamber motion, in which the swivel-chamber have a reciprocating motion in a horizontal plane, the combination with a rack, a pinion meshing therewith, a second pinion meshing with the first-mentioned pinion, a disk connected with the second-mentioned pinion and carrying a series of pins extending at right angles from the face thereof to engage a toothed segment or rack on the inner end of a swivel-chamber, of said swivel-chamber having a toothed segment or rack on its inner end, substantially as shown and described.

4. In a swivel-chamber motion, in which the swivel-chamber have a reciprocating motion in a horizontal plane, the combination with a rack, a pinion meshing therewith, a second pinion meshing with the first-mentioned pinion, a disk connected with the second-mentioned pinion and carrying a series of pins to engage a toothed segment or rack on the inner end of a swivel-chamber, of said swivel-chamber having a toothed segment or rack on its inner end, comprising two longer and tooth, an intermediate shorter tooth, and two recesses between the teeth, substantially as shown and described.

698,204. BLACKBOARD. OTTO LANGE, Jansburg, N. J. Filed Jan. 20, 1902. Serial No. 2,204. (No model.)

Claim.—The combination of a hinged lid or cover having its under side treated to form a blackboard, and a chalk-holding slot fixed to the under side of the cover or lid and having a groove in its face which is uppermost when the cover is erect, said groove being branched within the slot to form an overhanging portion at the front of the groove to retain the chalk in the groove when the cover is closed, substantially as described.

698,205. LADY'S SKIRT. GEORGE LANGE, Chicago, Ill. Filed Feb. 2, 1902. Serial No. 22,204. (No model.)

Claim.—1. As an improved article of manufacture, a skirt comprising a skirt-body and a flounce or ruffle therefor, and means detachably securing the latter to the former comprising a strip of open-work heading secured around the skirt-body, a strip of open-work heading secured around the upper margin of the flounce, and a cord laced through said heading-strips and locking them together, substantially as described.

2. As an improved article of manufacture, a skirt comprising a skirt-body, a flounce or ruffle to be applied to the lower portion thereof, and means detachably uniting said flounce to the skirt-body comprising a strip of open-work heading attached around the outside of the skirt-body, a

similar strip of heading attached around the upper margin of the flounce, and a cord laced through said heading-strips locking them together, substantially as described.

3. As an improved article of manufacture, a skirt comprising a skirt-body having a task formed therearound, and a flounce or ruffle therefor, a strip of open-work heading attached to the skirt-body beneath said task, a similar strip of heading attached to the upper margin of the flounce, and a cord laced through said heading-strips and thus detachably securing the flounce to the skirt-body, substantially as described.

4. As an improved article of manufacture, a skirt comprising a skirt-body having a task formed therearound and a slit or buttonhole formed therethrough beneath the task, and a flounce or ruffle therefor, a strip of open-work heading attached along its upper margin to the skirt-body beneath the task thereof, a similar strip of heading attached along its lower margin to the upper margin of the flounce, and an interlocking cord laced through said heading-strips and having its meeting ends passed through said slit and tied therebehind, substantially as described.

698,206. RAILROAD-CROSSING. CHARLES LILLIENBERG, Chicago, Ill. Filed June 23, 1901. Serial No. 60,202. (No model.)

Claim.—1. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an oppositely-disposed pair of horizontally-movable shifting-wedges for raising each pair of cross-rails, connections between each wedge of one pair and the adjacent wedges of the other pair, means for simultaneously operating said wedges to form a continuous track in either direction, substantially as described.

2. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an oppositely-disposed pair of horizontally-movable shifting-wedges for raising each pair of cross-rails and mechanism for simultaneously actuating said wedges to form a continuous track in either direction, substantially as described.

3. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an oppositely-disposed pair of horizontally-movable shifting-wedges for raising each pair of cross-rails, connections between each wedge of one pair and the adjacent wedges of the other pair and means for simultaneously operating said wedges to form a continuous track in either direction, substantially as described.

4. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an oppositely-disposed pair of horizontally-movable shifting-wedges for raising each pair of cross-rails, ball-and-socket levers connecting each wedge of one pair with the adjacent wedges of the other pair and operating-rods connected to said wedges, whereby as one pair of wedges is advanced, the other pair is withdrawn and a continuous track formed in one or the other direction, substantially as described.

5. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, a pair of oppositely-disposed shifting-wedges for rais-

ing each pair of cross-rails mounted to slide horizontally upon said base-plate and having flat upper bearing-surfaces for supporting said cross-rails in the raised position, connections between each wedge of one pair and the adjacent wedges of the other pair and means for simultaneously operating said wedges to form a continuous track in either direction, substantially as described.

6. In a railroad-crossing, the combination with a base-plate therefor and with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an oppositely-disposed pair of shifting-wedges for raising each pair of cross-rails, connections between each wedge of one pair and the adjacent wedges of the other pair, means for simultaneously operating said wedges to form a continuous track in either direction, laterally-projecting flanges on said cross-rails and means for engaging said flanges to limit their movement in an upward direction, substantially as described.

7. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an actuating-shifter for raising each one of said cross-rails, connections between each pair of adjacent shifters and means for operating said shifters to form a continuous track in either direction, substantially as described.

8. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an actuating-shifter for each one of said cross-rails, connections between each pair of adjacent shifters and operating-rods connected to each of said shifters, whereby any one of the same may be operated to form a continuous track in one or the other direction, substantially as described.

9. In a railroad-crossing, the combination with a base-plate therefor and with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rails for connecting the main rails of each track, an oppositely-disposed pair of reciprocating shifters for raising each pair of cross-rails, ball-and-socket levers connecting each shifter of one pair with the adjacent shifters of the other pair and mechanism for simultaneously moving one pair of shifters inwardly and the opposite pair outwardly to form a continuous track in one or the other direction, substantially as described.

10. In a railroad-crossing, the combination with the shutting main rails of the intersecting tracks, of an oppositely-disposed pair of movable cross-rails for connecting the main rails of each track, an oppositely-dis-

posed pair of horizontally-movable chifters for raising each pair of cross-rolls, notches in the sides of said chifters, bell-crank levers for connecting each adjacent pair of chifters mounted to swing in a horizontal plane and arranged to operatively engage said notches and operating means connected to one of said chifters, whereby a continuous track may be formed in either direction, substantially as described.

11. In a railroad-crowding, the combination with a base-plate therefor and with the shunting main rails of the intersecting tracks, of an oppositely-disposed pair of vertically-movable cross-rolls for connecting the main rails of each track, of an oppositely-disposed pair of wedges mounted to slide upon said base-plate for raising each pair of cross-rolls and having flat upper bearing-surfaces for supporting said cross-rolls in the raised position, circular notches in the sides of said wedges, studs on said base-plate, bell-crank levers for connecting each pair of adjacent wedges mounted to swing on said studs and having circular-headed ends for engaging said notches, operating-rods connected to each one of said wedges by any one of which said wedges may be shifted to form a continuous track in either direction, substantially as described.

12. In a railroad-crowding, the combination with the shunting main rails of the intersecting tracks, of tie-rods for connecting said main rails arranged slightly out of line therewith, oppositely-disposed pairs of vertically-movable cross-rolls adjacent said tie-rods and in line with said main rails, oppositely-disposed pairs of reciprocating chifters for raising said cross-rolls, connections between each pair of adjacent chifters and means for operating said chifters, whereby as one pair is advanced, the other is withdrawn to form a continuous track in one or the other direction, substantially as described.

13. In a railroad-crowding, the combination with a base-plate therefor and with the shunting main rails of the intersecting tracks, of abutments on said base-plate to which the ends of the main rails are attached, tie-rods connecting said main rails and arranged slightly out of line therewith, oppositely-disposed pairs of vertically-movable cross-rolls arranged adjacent said tie-rods and in line with said main rails, oppositely-disposed pairs of shifting-wedges for raising said cross-rolls mounted to slide upon said base-plate, bell-crank levers connecting each pair of adjacent wedges and means for simultaneously operating said wedges to form a continuous track in one or the other direction, substantially as described.

14. In a railroad-crowding, the combination with a base-plate therefor and with the shunting main rails of the intersecting tracks, of tie-rods connecting the ends of said main rails arranged slightly out of line therewith and having flanged openings, a center guide-plate, oppositely-disposed pairs of vertically-movable cross-rolls arranged intermediate said guide-plate and said tie-rods and in line with said main rails, oppositely-disposed pairs of shifting-wedges for raising said cross-rolls, connections between each pair of adjacent wedges and operating means for said wedges, whereby a continuous track may be formed in either direction, substantially as described.

15. In a railroad-crowding, the combination with the shunting main rails of the intersecting tracks, of oppositely-disposed pairs of vertically-movable continuous cross-rolls for connecting said main rails and mechanism arranged to be automatically operated by a train approaching in any direction to move said cross-rolls to form a continuous track in that direction, substantially as described.

16. In a railroad-crowding, the combination with the shunting main rails of the intersecting tracks, of oppositely-disposed pairs of cross-rolls for connecting said main rails, oppositely-disposed pairs of reciprocating chifters for raising said cross-rolls, connections between each pair of adjacent chifters, operating-rods connected to each chifter and device connected to said operating-rods and arranged adjacent the main rails of the intersecting tracks on each side of the crowding in position to be engaged by the wheels of an approaching train, whereby said cross-rolls will be automatically shifted to form a continuous track, substantially as described.

17. In a railroad-crowding, the combination with the shunting main rails of the intersecting tracks, of oppositely-disposed pairs of vertically-movable cross-rolls for connecting the main rails of each track, oppositely-disposed pairs of horizontally-reciprocating chifters for raising said cross-rolls, bell-crank levers connecting each pair of adjacent chifters, horizontal operating-rods connected to each chifter, rocking bars arranged adjacent the main rails on each side of the crowding in position to be engaged by the wheels of an approaching train and connections between said rocking bars and said operating-rods, substantially as described.

18. In a railroad-crowding, the combination with the shunting main rails of the intersecting tracks, of oppositely-disposed pairs of vertically-movable cross-rolls for connecting the main rails of each track, oppositely-disposed pairs of shifting-wedges for raising said cross-rolls, bell-crank levers connecting each pair of adjacent wedges, operating-rods connected to each of said wedges, interlocking pivoted levers engaging the ends of said operating-rods, rocking bars arranged adjacent the main rails of each track on each side of the crowding in position to be engaged by the wheels of an approaching train, rock-arms wherein said bars are mounted and

connecting-links between said bars and said pivoted levers, substantially as described.

19. In a railroad-crowding, the combination with the shunting main rails of the intersecting tracks, of oppositely-disposed pairs of vertically-movable cross-rolls arranged to connect the main rails of each track, oppositely-disposed pairs of reciprocating shifting-wedges for raising said cross-rolls, bell-crank levers connecting each pair of adjacent wedges, operating-rods connected to each of said wedges and a shifting-lever connected to one or more of said operating-rods, whereby a continuous track may be formed in either direction, substantially as described.

20. In a railroad-crowding, the combination with the main rails of the movable cross-rolls, means for shifting said cross-rolls to form a continuous track in either direction, a horizontal operating-rod for said means extending between said main rails, supporting-bar fixed in place outside of said main rails carrying clamped cross-plates between them, rock-arms carried by said clamps between said supporting-bar and said main rails, horizontal rocking bars positioned between said rock-arms and said rails and having laterally-projecting studs engaging the free ends of said rock-arms and connections between said rocking bars and said operating-rod, substantially as described.

698,907. PROCESS OF CLEARING WOOL. BILLS MARSHALL, Providence, R. I. Filed Dec. 27, 1900. Serial No. 41,395. (No opposi-tions.)

Claim.—1. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of said solvent, the process which consists in subjecting the wool to the action of water or suitable aqueous solutions and then to the action of a suitable acid or acid saline solution, for the purpose set forth.

2. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of said solvent, the process which consists in subjecting the wool to the action of water or suitable aqueous solutions, then treating the wool with an aqueous acid or acid saline solution and then removing the said acid or acid saline solution, substantially as described.

3. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of said solvent, the process which consists in subjecting the wool to the action of water or suitable aqueous solutions, then treating the wool with an aqueous acid or acid saline solution, then neutralizing said solution and then rinsing the wool, substantially as described.

4. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of said solvent, the process which consists in subjecting the wool to the action of water or suitable aqueous solutions, then treating the wool with an aqueous acid or acid saline solution, then removing the bulk of said solution, then neutralizing the residual acid solution and then rinsing the wool, substantially as described.

5. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of said solvent, the process which consists in subjecting the wool to the action of water or suitable aqueous solutions, then treating the wool with an aqueous acid or acid saline solution, and then removing said acid or acid saline solution, substantially as described.

6. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of said solvent, the process which consists in subjecting the wool to the action of a suitable acid or acid saline solution, for the purpose set forth.

7. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of the said solvent, the process which consists in subjecting the wool to the action of a suitable acid or acid saline solution and then removing the said acid or acid saline solution from the wool, substantially as described.

8. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of the said solvent, the process which consists in subjecting the wool to the action of a suitable acid or acid saline solution, then treating the wool with a neutralizing solution, then washing the wool, substantially as described.

9. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of the said solvent, the process which consists in subjecting the wool to the action of a suitable acid or acid saline solution, then treating the wool with a neutralizing solution, then washing the wool, substantially as described.

10. In the art of treating wool which has been subjected to the action of a volatile solvent and which wool still retains some of the said solvent, the process which consists in subjecting the wool to the action of a suitable acid or acid saline solution, then removing the bulk of said solution, then neutralizing the residual acid or acid saline solution and then rinsing the wool, substantially as described.

698,908. PROCESS OF CLEARING WOOL. BILLS MARSHALL, Providence, R. I. Filed Feb. 20, 1901. Serial No. 41,114. (No opposi-tions.)

Claim.—1. In the art of cleaning wool with volatile fat-solvents the improvement which consists in bringing in contact with the solution or solution obtained in any part of the apparatus an agent or agents which will prevent or correct the formation of an emulsion with the water present, substantially as described.

2. In the art of cleaning wool with volatile fat-solvents the improvement which consists in treating the solvent on the wool for the purpose of removing the same with an agent or agents which will prevent or correct the formation of an emulsion with any water present and which will not substantially decompose the natural crimp of the wool substantially as described.

3. In the art of cleaning wool with volatile fat-solvents the improvement which consists in treating the residual solvent on the wool for the purpose of removing the same with an agent or agents which will prevent or correct the formation of an emulsion with any water present and which will not substantially decompose the natural crimp of the wool, substantially as described.

698,909. PROCESS OF DEGREASING WOOL. BILLS MARSHALL, Providence, R. I. Filed Mar. 1, 1901. Serial No. 41,495. (No opposi-tions.)

Claim.—1. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then treating the wool with an aqueous solution of an agent which will transform or decompose the potash soaps of the wool, then subjecting the wool to the action of an agent to remove the transformed soaps, chemicals or fatty acids not free by the decomposition of the potash soaps, substantially as described.

2. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent, then treating the wool with an aqueous solution of an agent which will transform or decompose the potash soaps of the wool, then subjecting the wool to the action of an agent to remove the transformed soaps, chemicals or fatty acids not free by the decomposition of the potash soaps, substantially as described.

3. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then treating the wool with an aqueous solution of an agent which will transform or decompose the potash soaps of the wool, then removing the bulk of the solution from the wool, then subjecting the wool to the action of an agent to remove the transformed soaps, chemicals or fatty acids not free by the decomposition of the potash soaps, substantially as described.

4. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then treating the wool with an aqueous solution of an agent which will transform or decompose the potash soaps of the wool, then removing the bulk of the solution from the wool, then removing the last traces of solvent from the wool, then subjecting the wool to the action of an agent to remove the transformed soaps, chemicals or fatty acids not free by the decomposition of the potash soaps, substantially as described.

5. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent, then treating the wool with an aqueous solution of an agent which will transform or decompose the potash soaps of the wool, then removing the last traces of solvent from the wool, then subjecting the wool to the action of an agent to remove the transformed soaps, chemicals or fatty acids not free by the decomposition of the potash soaps, substantially as described.

6. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the residual solvent and the bulk of the potash compounds with water or other suitable aqueous solution which will not decompose the potash soaps, then treating the wool with an aqueous solution of an agent which will transform or decompose the residual potash compounds, then removing the last traces of solvent from the wool, then removing the transformed soaps, chemicals or precipitated fatty acids from the wool, substantially as described.

7. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent, then removing the residual solvent and the bulk of the potash compounds with water or other suitable aqueous solution which will not decompose the potash soaps, then treating the wool with an aqueous solution of an agent which will transform or decompose the residual potash compounds, then removing the last traces of solvent from the wool, then removing the transformed soaps, chemicals or precipitated fatty acids from the wool, substantially as described.

8. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the residual solvent

and the bulk of the potash compounds with water or other suitable aqueous solution which will not decompose the potash soaps, then removing the bulk of the solution from the wool, then treating the wool with an aqueous solution of an agent which will transform or decompose the residual potash compounds, then removing the last traces of solvent from the wool, then removing the transformed soaps, chemicals or precipitated fatty acids from the wool, substantially as described.

9. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent, then removing the residual solvent and the bulk of the potash compounds with water or other suitable aqueous solution which will not decompose the potash soaps, then removing the bulk of the solution from the wool, then treating the wool with an aqueous solution of an agent which will transform or decompose the residual potash compounds, then removing the last traces of solvent from the wool, then removing the transformed soaps, chemicals or precipitated fatty acids from the wool, substantially as described.

10. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the solvent and simultaneously transforming or decomposing the potash compounds on the wool, then removing from the wool the products resulting from this transformation or decomposition, substantially as described.

11. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the solvent and simultaneously transforming or decomposing the potash compounds on the wool, then removing the last traces of solvent from the wool, then removing from the wool the products from the transformation or decomposition of the potash compounds, substantially as described.

12. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the solvent by an agent which will decompose the soaps present on the wool, then treating the wool with a volatile fat-solvent to remove the fatty acids therefrom, substantially as described.

13. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the solvent by an agent which will decompose the potash soaps present on the wool, then removing the bulk of the decomposing agent, then treating the wool with a volatile fat-solvent to remove the fatty acids therefrom, substantially as described.

14. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the solvent by an agent which will decompose the soaps present on the wool, then treating the wool with a volatile fat-solvent to remove the fatty acids therefrom, then removing this latter solvent, substantially as described.

15. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent from the wool, then treating the wool with an aqueous solution of an agent to decompose the potash soaps present on the wool, then removing the fatty acids by a volatile fat-solvent, substantially as described.

16. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent from the wool, then treating the wool with an aqueous solution of an agent to decompose the potash soaps present on the wool, then removing the bulk of the decomposing solution, then removing the fatty acids by a volatile solvent, substantially as described.

17. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent from the wool, then treating the wool with an aqueous solution of an agent to decompose the potash soaps present on the wool, then removing the fatty acids by a volatile fat-solvent, then removing the latter solvent from the wool, then neutralizing or rinsing the wool or both, substantially as described.

18. In the art of cleaning wool, the process which consists in extracting the wool-fat by volatile solvent, then removing the bulk of the solvent from the wool, then treating the wool with an aqueous solution of an agent to decompose the potash soaps present on the wool, then removing the bulk of the decomposing solution, then removing the fatty acids by a volatile fat-solvent, then removing the latter solvent from the wool, then neutralizing or rinsing the wool or both, and then washing the wool.

698,910. PROCESS OF CLEARING WOOL. BILLS MARSHALL, Providence, R. I. Filed Mar. 1, 1901. Serial No. 41,496. (No opposi-tions.)

Claim.—1. In the art of cleaning wool the process which consists in subjecting the wool to the action of an agent to remove the potash soaps, then treating the wool from the bulk of the solvent liquid, then rinsing the wool with water, then treating the wool from the bulk of the

adhering water, then extracting the fat from the wool by a volatile solvent and then removing the solvent from the wool.

2. In the art of cleaning wool the process which consists in subjecting the wool to the action of an agent to remove the potash soaps, then treating the wool from the bulk of the adhering liquid, then treating the wool with a suitable acid, saline, or acid saline solution, then treating the wool from the bulk of the adhering liquid, then treating the wool without previous drying with a volatile solvent to remove the fat therefrom and then removing the solvent from the wool.

3. In the art of cleaning wool containing potash compounds, the process which consists in subjecting the wool to the action of an agent which will decompose or transform the potash soaps present, then removing the bulk of the adhering liquid from the wool, then extracting the fat from the wool without previous drying by a volatile solvent and then removing the solvent from the wool.

4. In the art of cleaning wool the process which consists in treating the wool with a solution of an agent which will deposit the fatty acids of the potash soaps on the fiber, then removing the bulk of the adhering liquid, then extracting the fat with a volatile solvent and then removing the solvent from the wool.

5. In the art of cleaning wool the process which consists in treating the wool with a solution of a suitable salt or acid or of both together, then removing the bulk of the adhering liquid, then subjecting the wool to the action of a volatile solvent and then removing the solvent from the wool.

698,211. PROCESS OF CLEANING WOOL WITH VOLATILE SOLVENTS. HILLS HARRISON, Providence, R. I. Filed Oct. 24, 1901. Serial No. 98,322. (No specimens.)

Claim.—1. In the art of cleaning wool with volatile fat-solvents the process which consists in first removing the bulk of the potash compounds from the wool, then impregnating the wool with the solution of an agent which will prevent emulsification of the water, potash compounds present and the volatile solvent subsequently introduced and then extracting the fat from the wool by means of a volatile fat-solvent.

2. In the art of cleaning wool with volatile fat-solvents the process which consists in first impregnating the wool with the solution of an agent which will prevent emulsification of the water, potash compounds present and the volatile solvent subsequently introduced, then extracting the fat from the wool by means of a volatile fat-solvent and then removing the volatile solvent from the wool.

3. In the art of cleaning wool with volatile fat-solvents the process which consists in first impregnating the wool with the solution of an agent which will prevent emulsification of the water, potash compounds present and the volatile solvent subsequently introduced, then extracting the fat from the wool by means of a volatile fat-solvent and then removing the volatile solvent from the wool.

4. In the art of cleaning wool with volatile fat-solvents the process which consists in first impregnating the wool with the solution of an agent which will prevent emulsification of the water, potash compounds present and the volatile solvent subsequently introduced, then extracting the fat from the wool by means of a volatile fat-solvent, then removing the bulk of the solvent from the wool and then eliminating the residual solvent.

5. In the art of cleaning wool with volatile fat-solvents the process which consists in extracting the grease with a volatile fat-solvent and then removing the residual solvent from the wool, both steps being performed in the presence of an agent which will prevent emulsification.

6. In the art of cleaning wool with volatile fat-solvents the process which consists in extracting the grease with a volatile fat-solvent in the presence of an agent which will prevent emulsification and then removing the residual solvent from the wool.

7. In the art of cleaning wool with volatile fat-solvents the process which consists in removing the residual solvent from the wool in the presence of a suitable acid, salt or acid salt which will prevent the solvent from clinging to the fiber and water present.

8. In the art of cleaning wool with volatile fat-solvents the process which consists in removing the residual solvent from the wool in the presence of a suitable agent or agents whereby the solvent is prevented from clinging to the fiber and water present.

9. In the art of cleaning wool with volatile fat-solvents the process which consists in first depositing the wool and then displacing the depositing agent with a volatile fat-solvent immiscible with the depositing agent.

10. In the art of cleaning wool with volatile fat-solvents, the process which consists in first depositing the wool, then displacing the depositing agent with a volatile fat-solvent immiscible with the depositing agent and then removing the volatile solvent from the wool.

11. In the art of cleaning wool with volatile fat-solvents, the process which consists in first depositing the wool, then displacing the depositing agent with a volatile fat-solvent immiscible with the depositing agent, then removing the bulk of the solvent from the wool and then eliminating the residual solvent.

698,212. ADJUSTABLE RATCHET DEVICE. CHARLES A. HILLMAN, Reading, Pa. Filed Feb. 11, 1902. Serial No. 92,494. (No model.)

Claim.—In an adjustable ratchet device, a toothed frame A having an elongated opening, an operating arm B extending through said opening, a pawl pivoted to said arm and adapted to engage the teeth on said frame, a shoe C, a foot-plate D formed on said shoe, said shoe pivoted to the free end of said arm, depending rod E, and a pin F secured to said rod E and adapted to engage a slot in said pawl, substantially as set forth.

698,213. WAGON TRUCK. JOHN A. McHARRY, Chicago, Ill. Filed Jan. 22, 1902. Serial No. 91,741. (No model.)

Claim.—1. A truck, consisting of wheel, a body portion, a folding supporting-frame at one end of the body portion, a brake-beam and brake-shoes at the other end, a bar disposed to said brake-beam, and an eccentric connection between said bar and the folding frame, whereby when the latter is folded the bar is moved and the brakes set or freed as the case may be.

2. A truck, consisting of wheel, a body portion mounted thereon, a supporting-frame at one end thereof, a bar whereby such supporting-frame is pivoted to the truck, an eccentric loop in said bar, a rod connected therewith, a brake-beam and brake-shoes at the other end of the truck, and a connection from the same to said bar, so that when the supporting-frame is lowered the brake-shoes are set and when the supporting-frame is folded up out of position the brake-shoes are freed from the wheel.

3. A truck, consisting of wheel, a body portion, a folding supporting-frame at one end of the body portion, a brake-beam and brake-shoes at the other end, a bar connected to said brake-beam, an eccentric connection between said bar and the folding frame, whereby when the latter is folded the bar is moved and the brakes set or freed as the case may be, and a locking device to lock the supporting-frame down in its supporting position.

4. A truck, consisting of wheel, a body portion mounted thereon, a supporting-frame at one end thereof, a bar whereby such supporting-frame is pivoted to the truck, an eccentric loop in said bar, a rod connected therewith, a brake-beam and brake-shoes at the other end of the truck, a connection from the same to said bar, so that when the supporting-frame is lowered the brake-shoes are set and when the supporting-frame is folded up out of position the brake-shoes are freed from the wheel, and a locking device to lock the supporting-frame down in its supporting position.

5. A truck, consisting of wheel, a body portion, a folding supporting-frame at one end of the body portion, a brake-beam and brake-shoes at the other end, a bar connected to said brake-beam, an eccentric connection between said bar and the folding frame, whereby when the latter is folded the bar is moved and the brakes set or freed as the case may be, and a locking device to lock the supporting-frame up in its idle position.

6. A truck, consisting of wheel, a body portion mounted thereon, a supporting-frame at one end thereof, a bar whereby such supporting-frame is pivoted to the truck, an eccentric loop in said bar, a rod connected therewith, a brake-beam and brake-shoes at the other end of the truck, a connection from the same to said bar, so that when the supporting-frame is lowered the brake-shoes are set and when the supporting-frame is folded up out of position the brake-shoes are freed from the wheel, and a locking device to lock the supporting-frame up in its idle position.

7. A truck comprising wheel, a framework mounted on said wheel, a supporting frame attached to said framework and adapted to be folded

down into a vertical position to engage the ground and to hold the framework from rotating on or with the wheel, and brake-shoes on the framework and connected with the supporting-frame so that when the latter is moved into position to support the framework the brake-shoes are correspondingly moved to engage the wheel.

8. A truck comprising wheel, a frame supported on said wheel, a supporting-frame attached to said framework on one side of said wheel, brake-shoes attached to said framework on the opposite side of said wheel and a connection from the supporting-frame to said brake-shoes whereby when the framework is moved into position the brake-shoes are correspondingly operated.

9. A truck comprising wheel, a framework mounted on said wheel, a supporting-frame pivoted to said framework so as to fold thereon or project therefrom and engage the ground, brake-shoes supported on the framework and a connection from the brake-shoes to the supporting-frame so that when the latter is folded into position to support the framework the brake-shoes are correspondingly operated to engage the wheel.

10. A truck, comprising a pair of wheels, a framework pivotally mounted thereon, a folding frame attached to the framework and adapted to fold down so as to engage the ground and with the wheels support the framework in a substantially horizontal position, brake-shoes adapted to engage the wheels when the supporting-frame is in engagement with the ground, and connections from the brake-shoes to such supporting-frame, so that when the latter is operated the former are set.

698,214. PROCESS OF FLANGING METALLIC TUBES. NORMAN McKEOWN, Cleveland, Ohio. Filed July 12, 1901. Serial No. 67,699. (No specimens.)

Claim.—The described process of flanging metallic tubes, which consists in fitting upon the tube two or more collars, leaving uncovered between them enough of the tube to form the flange or flanges; in passing an electric current through said tube and wire whereby the uncovered parts of said tube are heated to a welding heat, and in applying outward pressure upon said tube and said collars whereby the uncovered parts of the tube are thrown outward and the flange is pressed into shape and the meeting faces of the metal welded together between said collars.

698,215. FRETWORK DRAFT-RIGGING APPLIANCE. THOMAS L. McKIM, Boston, Pa. Filed Feb. 6, 1902. Serial No. 92,399. (No model.)

Claim.—1. In combination with the bearings secured to the draft-timbers, and end and intermediate followers located therein, laterally-compressible spring-plates, adapted to move bodily in a longitudinal direction, means for compressing said spring-plates and causing frictional contact with the bearings, and springs interposed between the intermediate and the rear-end follower, substantially as and for the purpose set forth.

2. In combination with the bearings secured to the draft-timbers, end and intermediate followers located therein, and laterally-compressible and longitudinally-movable spring-plates, means for compressing the laterally-located spring-plates, axially-arranged coil-springs between the intermediate follower, and the rear-end follower, and means for moving the end followers, substantially as and for the purpose set forth.

3. In combination with the bearings secured to the draft-timbers and end and intermediate followers located therein, laterally-compressible spring-plates mounted in closed-bottomed laterally-movable supporting-bases having their adjacent vertical faces beveled rearwardly, carry-bars secured to the bearings and supporting the bases, and a longitudinally-movable push-bar formed with a beveled forward terminal for spreading the bases, and means for reciprocating the push-bar, and spring-supporting bases, substantially as and for the purpose set forth.

4. In a draft-rigging such as described and provided with laterally-compressible spring-plates supported in movable bases, and longitudinally-compressible coil-springs; a forward and movable partition or follower, and followers intermediate of the spring-plates and coil-springs, a rear-end follower having a central stem for supporting the coil-springs, and having its forward terminal adapted to spread apart the spring-plate-supporting bases, substantially as hereinbefore set forth.

5. In a draft-rigging such as described, the laterally and longitudinally-movable spring-plate-supporting bases, open on one end, top and on one side, and having the rear end closed to constitute an intermediate follower, substantially as and for the purpose set forth.

6. In a draft-rigging such as described and embodying longitudinally-movable and followers, and intermediate follower and laterally-movable spring-supporting bases between the forward and follower, and the intermediate follower, flat spring-plates located within the supporting-bases and having their ends abutting respectively against the said followers, and constituting braces between said followers, and coil-springs between the rear-end follower and the intermediate follower, substantially as and for the purpose set forth.

7. In a draft-rigging such as described, the rear-end follower F formed with an axial stem G, and separable wedge-block I, connected by a removable bolt or pin H, substantially as hereinbefore set forth.

8. In combination with the bearings secured to the draft-timbers, end and intermediate followers and yokes located therein, and coil-springs between the intermediate and a rear-end follower having a central stem terminating in a wedge-shaped head; laterally-movable bases having inclined adjacent faces located each side of the wedge-shaped head of the follower-stem, and adapted to receive and compress friction-producing springs, substantially as hereinbefore set forth.

698,216. HINGE. WAMMAL P. NEWMAN, Watertown, Mass. Filed June 22, 1901. Serial No. 65,699. (No model.)

Claim.—1. A hinge comprised of a vertically-sliding plate and two leaves, the upper leaf provided with a wing substantially as and for the purposes specified.

2. A hinge comprised of a vertically-sliding plate and two leaves, each leaf provided with a wing substantially as and for the purposes specified.

3. A hinge having an automatically-locking plate and comprised of two leaves projecting from a tubular part and a projecting bar formed on upper leaf of hinge extending on its inner face from tubular part for opening said plate, substantially as shown and described.

4. A hinge having two leaves projecting from tubular parts, a hub

leg-plate and means for operating same and a projecting bar formed on lower leaf of hinge and extending from the tube upon inner face of the lower leaf, substantially as shown and described.

5. A hinge comprised of two leaves, each of which is provided with a socket and projections or wings extending upon and across their inner face, and the lower hinge having a recess, a pin having a knob and being vertically movable in said recess and lower socket to engage the upper socket, and a spiral spring to support said pin, substantially as shown and described.

698,217. SANITARY TRAP. ALBERT E. NEWTON, Providence, R. I. Filed Mar. 1, 1900. Serial No. 4,390. (No model.)

Claim.—In a sanitary trap, the combination with the body of the vessel the annular lip *a* and the neck *c*, of the hard-metal ring *B* the groove *d*, the ribs *e* and the seats *f* on the ring, the metal of the neck extending into the seats and the recess between the ribs, whereby the ring is secured to the vessel, as described.

698,218. ELECTRIC-LAMP SOCKET. HERBERT FORD, New York, N. Y., assignor to the Jordan-Bitner Electric Company, New York, N. Y., a Corporation of New York. Filed Jan. 16, 1901. Serial No. 29,864. (No model.)

Claim.—1. The combination with a cap and base of insulating material, and means for receiving electric conductors between the same and a clamping device for holding the same thereto, of a screw-socket within the cap of insulating material, a central metal plate, metallic sleeves connected respectively to said parts and extending through perforations in the lower portion of the cap and pointed devices passing through said sleeves and adapted to penetrate the covering of the electric conductors to contact with the wires therein, substantially as set forth.

2. The combination with a cap and base of insulating material, and means for receiving electric conductors between the same and a clamping device for holding the same thereto, of a screw-socket within the cap of insulating material, a central metal plate, metallic sleeves connected respectively to said parts and extending through perforations in the lower portion of the cap and pointed devices passing through said sleeves and adapted to penetrate the covering of the electric conductors to contact with the wires therein, and clamping screws or bolts at points through the lower portion of the cap intermediate to the aforesaid devices and by which the said screw-socket is firmly held to the cap of insulating material, substantially as set forth.

3. The combination with the cap and base of insulating material, and means for receiving electric conductors between the same and a clamping device for holding the same thereto, of a screw-socket *f* within the cap of insulating material and a screw-sleeve *10* connected therewith and passing through a perforation in the base of the cap, a central metal plate *A* and a screw-sleeve *11* connected therewith and also passing through a perforation in the base of the cap, and screws *12* with sharp points on their advancing ends movable through the screw-sleeves *10* and *11* and adapted to penetrate the insulating-covering of the conductors held between the cap and the base, the points making metallic and electrical contact with the wires of the conductors, substantially as set forth.

4. The combination with the cap and base of insulating material, and means for receiving electric conductors between the same and a clamping device for holding the same thereto, of a screw-socket *f* within the cap of insulating material and a screw-sleeve *10* connected therewith and passing through a perforation in the base of the cap, a central metal plate *A* and a screw-sleeve *11* connected therewith and also passing through a perforation in the base of the cap, and screws *12* with sharp points on their advancing ends movable through the screw-sleeves *10* and *11* and adapted to penetrate the insulating-covering of the conductors held be-

tween the cap and the base, the points making metallic and electrical contact with the wires of the conductors, the outer ends of the screw-sleeves *10* and *11* being spread or flared into the recesses receiving the conductors for the purpose of securely fastening the screw-sleeves to the lower portion of the cap, substantially as set forth.

698,219. HOOKED-BANDS. SAMUEL E. PALMER, New York, N. Y. Filed Nov. 16, 1900. Serial No. 28,807. (No model.)

Claim.—A fastener for a socket having a band encircling the neck, having means at its center for securing it in the socket, spring gripping devices at its ends engaging the band and secured thereto, and adapted to engage a collar and hold said band tightly against the said collar, substantially as shown and described.

698,220. GRASSHOPPER-BLACK SULPHUR DYE AND METHOD OF MAKING SAME. AUGUST FRIEDMAN, Brugg, Switzerland, assignor to the Firm of Chemische Fabrik Brugg A. G., formerly Dr. Baumgarten & Co., Brugg, Switzerland. Filed Sept. 6, 1901. Serial No. 74,866. (No specimens.)

Claim.—1. The described process for the manufacture of grasshopper-black, colored, directly-dyeing dyestuff for cotton, by heating a pentachloro sulfonate with sulfuric acid.

2. As a new article of manufacture, the described grasshopper-black, colored dyestuff, derived from a pentachloro sulfonate, which dye is recommended cotton, is a bath containing alkali, sodium carbonate and common salt, in grasshopper-black shades fast to light.

698,221. FLOUR-MILL. GEORGE F. LAMBERT, Boston, Mass. Filed Sept. 20, 1901. Serial No. 75,907. (No model.)

Claim.—1. An apparatus of the character described, comprising a primary grinding-mill, a primary belt, a conveyor for delivering the ground material from the grinding-mill to the belt, a delivery-spout for the belt material, a primary screening apparatus having means for dividing the screened product into different grades and having spouts for delivering the same, a secondary grinding-mill, a conveyor for delivering the unscreened material to said secondary mill, a secondary belt having means for separating the still further reduced material into different grades, means for delivering the reduced material from the secondary grinding-mill to the secondary belt, a secondary screening apparatus having means for separating the material into different grades and having spouts for delivering said grades of material separately, and means for delivering the unsifted material from the secondary belt to the said secondary screening apparatus.

2. An apparatus of the character described, comprising a primary grinding-mill, a primary belt, a conveyor for delivering the ground material from the grinding-mill to the belt, a delivery-spout for the belt material, a primary screening apparatus having means for dividing the screened product into different grades and having spouts for delivering the same, a secondary grinding-mill, a conveyor for delivering the unscreened material to said secondary mill, a secondary belt consisting of a reel having its holding-cloth divided into a plurality of sections differing as to the fineness of their meshes, means for delivering the reduced material from the secondary grinding-mill to the secondary belt, a plurality of compartments below the sections of said reel, means for separately delivering the material from the said compartments, means for delivering the unscreened material from the secondary belt, and a secondary screening apparatus consisting of a casing having a plurality of independent compartments with outlets therefrom, and a reciprocating screen arranged to receive the unscreened material from the secondary belt, and having sections of fine-mesh material of different textures, covering all but the final compartment and adapted to deliver the unscreened material to said final compartment.

698,222. WASHING-MACHINE. BERTON FORD, Port Wayne, Ind. Filed Nov. 2, 1900. Serial No. 26,811. (Model.)

Claim.—1. The combination of the said vessel, a lid therefor, an agitator-shaft mounted in said lid and provided with a pinion, a bracket attached to the top of the said vessel, a frame pivoted to said bracket and attached to the lid to form a hinge therefor, and gearing carried by said frame for actuating the agitator-shaft.

2. The combination of the said vessel, a lid therefor, an agitator-shaft mounted in said lid and provided with a pinion, a bracket attached to the top of the vessel, a frame pivoted to said bracket and attached to the lid to form a hinge therefor, and gearing carried by said frame for actuating the agitator-shaft, with a locking-piece provided with a handle and pivoted to an ear on the bracket and having its engaging portion in- cluding upward and curved to form a cam, a curved plate attached to the neck to form a shield, catches formed on both ends of the plate adapted to engage the locking-piece, the lower one engaging first the upper part of said cam, and adapted to be forced backward by the operation of the cam.

698,223. SASH-OVERHAUL BOX. LOUIS FRIEDMAN, Philadelphia, Pa. Filed Mar. 11, 1901. Serial No. 68,006. (No model.)

Claim.—The combination of the expandable rod *1*, bracket-extensions *7* secured to each end of said rod, the inner ends of said brackets being bent inwardly and backwardly in the rear of the rod, outwardly-extending points *6*, formed on the ends of said brackets, and auxiliary points *11* formed on each end of the rod, whereby said rod can be attached either to the edges of the sash or to the window-frame, substantially as described.

698,224. CASTER. SAMUEL E. PALMER, New York, N. Y. Filed Feb. 2, 1901. Serial No. 68,380. (No model.)

Claim.—1. In a caster, a ball having a socket therein and a plate, one end of the plate resting in and bearing against the lower end of the socket as and for the purpose set forth.

2. In a caster, a ball having a socket therein, a bearing-plate at the inner end of the socket, a plate of less diameter than the diameter of the socket, one end of which is in contact with the bearing-plate and means for holding the plate in the socket.

3. In a caster, a ball having a socket therein, the upper end of the socket being of larger diameter than the lower end, a plate in the socket the lower end of which bears against the inner end of the socket, anti-

friction-balls in the enlarged part of the socket and surrounding the plate, a flange on the plate, a plate fastened to the ball having an opening therein of larger diameter than the diameter of the plate and through which the plate passes, said plate being adapted to bear against the flange to hold the plate in the socket.

4. In a caster, a ball having a socket therein, a plate in the socket of smaller diameter than the diameter of the socket, one end of the plate resting against the inner end of the socket and supporting the weight brought on the center, the parts being so arranged that this end of the plate will be in front of the vertical axis of the ball when the center is in use and that there may be a free or "wobbly" movement of the plate in its socket.

5. In combination, a leg of a piece of furniture having a socket therein, a ball also having a socket therein, a plate inserted in each socket, one end of the plate being rigidly secured in one of the sockets and the other end of the plate moving free in the other socket as and for the purpose set forth.

6. In combination, a leg of a piece of furniture, having a socket therein, a ball also having a socket therein, a plate inserted in each socket one end of the plate being secured in one of the sockets and the other end of the plate resting against the inner end of the other socket, which is tapered and of greater diameter than the diameter of the plate, so that the end of the plate which rests against the end of the socket will support the weight brought upon the center and when the center is in motion that end of the plate will be in advance of the vertical axis of the ball and the ball will be permitted to have a "wobbly" motion.

7. In combination, a leg of a piece of furniture having a socket therein, a vertical plate having one end inserted in the socket, a ball directly under the leg of the furniture having a vertical socket therein of greater diameter than the diameter of the plate, the lower end of the plate inserted in the said socket, the lower end bearing directly against the inner end of the socket and supporting the weight brought on the leg of the furniture, means for holding the ball and plate together but to permit the ball to have a free or "wobbly" motion about the plate as and for the purpose set forth.

698,225. INCANDESCENT GAS-LAMP. ALVIN B. RUSSELL, Chicago, Ill. Filed July 1, 1901. Serial No. 68,708. (No model.)

Claim.—1. In an incandescent lamp, in combination, a Bunsen tube; a mantle-supporting shell; and a spring in said shell, mounted above the upper end of the tube, for supporting the shell with relation to the tube.

2. In an incandescent lamp, in combination, a Bunsen tube; a central coil-spring mounted on its base above said tube; and a mantle-supporting shell surrounding said central spring, and resting upon the smaller end of said central spring.

3. In an incandescent lamp, in combination, a Bunsen tube; a central coil-spring mounted on its base above said tube; and a mantle-supporting shell surrounding said central spring, said shell having within its upper portion an arm resting upon the smaller end of said central spring, for supporting said shell.

4. In an incandescent lamp, in combination, a lamp-gallery; a Bunsen tube; a mantle-supporting shell; and a spring extending from a point

above the upper end of said Benson tube, which spring supports said mantle-supporting shell with relation to said tube.

5. In an incandescent lamp, in combination, a lamp-gallery; a Benson tube; a spring-supporting tube telescoping with said Benson tube; a mantle-supporting shell; and a coil-spring seated in the upper end of said spring-supporting tube, for supporting the mantle-supporting shell.

6. In an incandescent lamp, in combination, a lamp-gallery; a Benson tube; a spring-supporting tube telescoping with said Benson tube; a spring mounted in said spring-supporting tube; and a mantle-supporting shell having means for mounting said shell on said spring.

7. In an incandescent lamp, in combination, a lamp-gallery; a Benson tube; a spring-supporting tube telescoping with said Benson tube; a conical coil-spring mounted in said spring-supporting tube; a mantle-supporting shell having means for supporting said shell upon said spring; and means for attaching the mantle to said shell.

8. In a means for supporting incandescent mantles, in combination, a coil-spring; a guide-rod; a mantle-supporting shell having means for supporting said shell upon said spring; and means for attaching the mantle to said shell.

9. In a means for supporting incandescent mantles, in combination, a coil-spring; a guide-rod extending centrally through said spring; and a mantle-supporting shell having means for supporting said shell upon said spring and guiding it upon said guide-rod.

10. In a means for supporting incandescent mantles, in combination, a conical coil-spring; a guide-rod extending centrally of said spring; and a mantle-supporting shell having an arm within the upper portion of said shell, for supporting said shell upon said spring and for guiding it upon said guide-rod.

11. In an incandescent lamp, in combination, a spring-supporting tube; a conical coil-spring supported by said tube; a guide-rod extending centrally of said spring; a mantle-supporting shell having an arm within the upper portion of said shell, for supporting said shell upon said spring and for guiding it upon said guide-rod; and means for attaching the mantle to said shell.

698,226. PICKING-UP APPLIANCE FOR BALLS EDWARD R. ROBERTS, Claughton, near Birmingham, England. Filed Jan. 14, 1902. Serial No. 29,640. (No model.)

Claim.—1. A device for the purpose specified, comprising a skeleton receptacle having a flat bottom formed of spaced and substantially parallel connectors of flexible material, extending across from side to side and strained, substantially as set forth.

2. A device for the purpose specified, comprising a receptacle having a skeleton frame with open sides and bottom, and connectors of flexible material strained across said sides and bottom in straight lines, the contiguous connectors being parallel with each other, substantially as set forth.

3. Is an appliance for picking up balls, the combination of a pair of open frames of any suitable shape, placed one above the other at a suitable distance apart, corner-pieces adapted to fasten said frames together at a suitable distance apart, and made so as to enclose outward, and elastic or flexible strips or cords at sides and bottom of said frames forming a grid-like structure between which the balls can be slipped through, substantially as described.

698,227. SHELF-HOOK. CHARLES A. SCHRAMM, San Diego, Cal. Filed Nov. 20, 1901. Serial No. 23,145. (No model.)

Claim.—A shelf-hook made of a single piece of wire having its ends pointed and turned downward and spaced apart, said wire being bent at right angles at points T and designed to engage over the edge of a shelf, with the horizontal portions of the wire, intermediate the points T and the downwardly-bent ends, adapted to rest upon the upper surface of a shelf, and the vertical portion of the wire to bear against the edge of the shelf, said wire being bent upon itself at its longitudinal center, forming

a flexible tongue C, the sections of the wire forming the tongue being in contact with each other, and having a vertical play between the portions of the wire which are designed to engage the edges of a shelf, the sections of the wire at the base of the flexible tongue being bent at an inclination to form a hook, which is reinforced by bending the two sections of the wire upon themselves underneath the hook, the base of said tongue having a bearing against the portions of the wire underneath said hook at points H, substantially as shown and described.

698,228. CHAIR-TIP. GEORGE C. SCOTT, Boston, Mass. Filed July 2, 1901. Serial No. 27,422. (No model.)

Claim.—1. A chair-tip comprising an apertured yielding washer engaging the lower end of the chair-leg, and an apertured facing-block counterbored on the under face thereof and engaging the washer, the aperture in the facing-block registering with that of the washer and having a nail passed through said registering apertures to engage in the chair-leg with the head of the nail received in said counterbored portion of the facing-block, substantially as described.

2. A chair-tip comprising outwardly-bulged apertured spring-washers, and an apertured facing-block, the washers being interposed between the chair-leg and the facing-block with means passing through the facing-block and washers and engaging in the chair-leg, substantially as described.

3. A chair-tip comprising outwardly-bulged apertured spring-washers and an apertured facing-block with the bulged portions of the washers contacting with one another and having their opposite faces contacting with the facing-block and the chair-leg with means for securing the washers and facing-block to the chair-leg, substantially as described.

698,229. PRESS FOR BALING HAY, COTTON, &c. JAMES T. SCOTT, Buffalo, Ala. Filed Dec. 21, 1901. Serial No. 26,927. (No model.)

Claim.—In combination, a baling-chamber, a follower adapted to move therein, a stem composed of spaced parallel bars attached to the

follower, a turn-post passed through the space formed between the said parallel bars, ropes or cords attached at one end to the turn-post and adapted to wind reversely thereon and having their opposite ends attached, respectively, to the follower and the outer end of the follower-stem, upper and lower cross-bars having the stem of the follower passed between them, a catch at the outer end of the stem to engage one of the said cross-bars, a sweep applied to the turn-post, and a pinion for connecting the stem with the sweep when dumping the charges and disconnected from the sweep when pressing the bale, substantially as set forth.

698,280. GRAIN-SHOCKING ATTACHMENT FOR HARVESTING-MACHINES. LOUIS I. SPARKS, Chicago, Ill., administrator of George H. Sparkling, deceased, assignor to McCormick Harvesting Machine Company, Chicago, Ill. Filed Feb. 27, 1901. Serial No. 69,886 (No model.)

Class.—1. A shocking attachment for self-binding harvesters having, in combination, a main frame, a shaft secured near the center thereof and at a right angle thereto for pivotally supporting the shocker on the harvester-frame, a bundle-receiving cradle hinged to swing transversely to the movement of the shocker; a frame projecting transversely from the main frame across the cradle, a rock-shaft, mounted on the outer side of said frame parallel with the main supporting-frame, and carrying compressing and holding arms, means for rocking said shaft and arms, means for swinging the cradle on its hinges so as to deposit the shock on the ground, and means for rocking the cradle horizontally out of the way of the shock.

2. A shocking attachment for self-binding harvesters having, in combination, a main frame, a shaft secured near the center thereof and at a right angle thereto for pivotally supporting the shocker on the harvester-frame, a bundle-receiving cradle hinged so as to swing transversely to the movement of the shocker, knottin device mounted on the main frame, a frame projecting transversely from the main frame across the cradle, a rock-shaft mounted in the outer side of said frame, parallel with the main supporting-frame and carrying a needle-arm for passing the binding-cord to the knottin device, means for rocking the needle-shaft, means for swinging the cradle on its hinges so as to deposit the shock on the ground, and means for rocking the cradle horizontally out of the way of the shock.

3. In combination with a self-binding harvester, a shocking-cradle lying parallel with and beneath the binder-deck, when in its receiving position, said cradle being pivoted so as to tilt forwardly and downwardly to a substantially vertical position to deposit the shock, and being also pivoted to swing rearwardly and forwardly toward the side of the harvester out of the way of the shock as the machine advances.

4. In combination with a self-binding harvester, a shocking-cradle pivoted to tilt in a vertical plane parallel with the outer edge of the binder-table, and swing rearwardly and toward the binder-deck, the handle-receiving portion of the cradle being divided transversely so that the rear portion will pass above the binder-deck and the front portion below the same.

5. A shocking attachment for self-binding harvesters comprising, in combination, a main frame, a shaft secured near the center thereof and at a right angle thereto for pivotally supporting the shocker on the harvester-frame, a bundle-receiving cradle hinged to swing in a plane transverse to the main frame, a frame projecting transversely from the main frame across the cradle, an arm depending from said frame, and a similar arm depending from the main frame to support and guide the shock when the shocker is tilted to its discharging position.

6. A shocking attachment for self-binding harvesters having, in combination, a main frame, a shaft secured near the center thereof and at a right angle thereto for pivotally supporting the shocker on the harvester-frame, a bundle-receiving cradle hinged to swing transversely to the movement of the shocker, a frame projecting from the main frame across the cradle, a shaft mounted on the outer side of said frame, parallel to the main frame, a hook or latch secured to said shaft and adapted to engage the outer edge of the shocking-cradle, means for rocking the shaft and hook, means for swinging the cradle, and means for tilting the main frame.

7. A shocker-cradle consisting of two side bars, two bow-shaped end bars pivoted at a distance from each other to said side bars, intermediate bow-shaped rods also pivoted to the side bars, links connecting the rods to the end bars, and springs resisting the swinging of the bow-shaped bars and rods on their pivots.

8. A shocker-cradle consisting of two side bars, two bow-shaped end bars pivoted at a distance from each other to said side bars, a curved rod secured to one end bar and extending through an opening in one of the side bars, a coil-spring mounted on the curved rod and bearing at one end on an abutment of the curved rod and at the other on said side bar, a similar curved rod mounted on the other side bar and passing through an opening in the other bow-shaped end bar, a coil-spring on said rod bearing at one end against the end bar and at the other against an abutment on the curved rod, and a series of bow-shaped rods pivoted at their ends in the two side bars of the cradle and linked to the end bars.

9. In combination with a harvester having an adjustable binder, a tilting shocker, an adjustable shock-binder on said shocker, and means for adjusting the binders simultaneously in any position of the shocker.

10. The combination with a harvester having an adjustable binder, a tilting shocker, an adjustable shock-binder on said shocker, a loosely-rotating gear concentric with the shocker-pivot, and two rack-bars meshing with and free to swing about said gear, one of said bars being connected with the harvester-binder, and the other with the shock-binder.

11. In a shocker for self-binding harvesters, a main frame swinging about a pivot on the harvester and carrying the bundle-receiving cradle, a shock-binder mounted on said main frame, a segmental rack secured to the harvester-frame concentric with the pivot of the shocker, and a knottin driving-shaft mounted in bearings on the main shocker-frame and having a gear which meshes with the segmental rack.

12. In a shocker for self-binding harvesters, a main frame swinging about a pivot on the harvester and carrying the bundle-receiving cradle, a shock-binder frame mounted on said main frame, a needle-shaft on the outer side of the binder-frame, a crank-shaft in bearings on the main shocker-frame, a curved bracket on the harvester-frame concentric with the shocker-pivot and provided with a cam-slot having a straight portion and a curved end portion, said cam-slot engaging a crank on the crank-shaft, and means connecting the crank-shaft with the needle-shaft.

13. In a shocker for self-binding harvesters, a main frame swinging about a pivot on the harvester, a bundle-receiving cradle hinged to said main frame, a curved bracket on the harvester-frame concentric with the pivot of the shocker and provided with a cam-slot formed with a straight portion and a curved end portion, a rock-shaft mounted in bearings on the main shocker-frame and carrying a crank which engages the cam-slot, and connections between the rock-shaft and the bundle-receiving cradle for swinging the same.

14. In a shocker for self-binding harvesters, a main frame swinging about a pivot on the harvester, a shock-binder thereon, a bundle-receiving cradle hinged to said main frame, a curved bracket on the harvester-frame, concentric with the pivot of the shocker and provided with a cam-slot formed with a straight portion and a curved portion at each end, a tubular rock-shaft mounted in bearings on the main shocker-frame and carrying a crank which travels in the straight portion and one of the curved end portions, connections between the tubular crank-shaft and the shocker-cradle, a second crank-shaft carried at one end in the tubular crank-shaft and at the other in a bearing on the main shocker-frame, a crank on said shaft traveling in the straight portion and the second curved

portion of the cam-shaft, and connections between the second crank-shaft and the needle-shaft of the check-binder.

15. In a checker for self-binding harvesters, a main frame swinging about a pivot on the harvester, a U-shaped check-binder frame having one arm sliding on the checker-frame, a knotting mechanism carried on said arm, a knotted-shaft mounted on the checker-frame having a gear at one end and a groove-and-splice connection with the knotted-wheel, a segmental rack on the harvester-frame engaging the gear on the knotted-shaft, a tubular crank-shaft mounted on the checker-frame, a second crank-shaft having one end secured within the tubular shaft and the other is a bearing on the checker-frame, a crank connected for rotation to said shaft but sliding longitudinally thereon, the hub of said crank being held by a bearing-sleeve on the sliding binder-frame, a needle-shaft on the outer arm of the sliding binder-frame, a pinion connecting the crank on the last-mentioned crank-shaft with a crank on the needle-shaft, a curved bracket on the harvester-frame, concentric with the pivot of the checker and provided with a cam-disk formed with a straight portion and two curved end portions, cranks on the tubular shaft and the second crank-shaft which travel in the cam-disk, a handle-receiving cradle hinged to the main checker-frame, and connections between the tubular crank-shaft and the cradle for swinging the same.

16. A check-binder having a main frame, carrying the necessary shafts and gearing for operating the check-binder and other parts, and swinging in a plane parallel with the outer edge of the binder-table, in combination with a harvester binder-table projecting over the checker-frame to protect the gearing thereon, and having at its rear outer edge a hinged portion which turns up out of the way as the rear end of the checker-frame rises.

698,281. WASHING-JACK. CHARLES SHANNAN, Youngstown, Ohio. Filed Dec. 7, 1899. Serial No. 58,922. (No model.)

Claim.—1. A washing-jack for vehicle-wheels comprising a portable base constructed to rest flat upon the ground or floor, rolling supports carried by the base and arranged to hold a wheel thereon in a plane elevated above the ground-level, and guides carried by the base and arranged to direct the wheel on and off the supports.

2. A washing-jack for vehicle-wheels comprising a base having oppositely-located inclined wheel-guides, and rolling supports for sustaining thereon the wheel, said supports being arranged in the interval between the opposite guides, and adapted to support the wheel in a plane above the ground-level.

3. A washing-jack for vehicle-wheels comprising a base constructed to rest flat upon the ground or floor, and a pair of wheel-supporting rollers held by the base in a plane elevated from the ground or floor and arranged in spaced parallel relation in the same horizontal plane.

4. A washing-jack for vehicle-wheels comprising a base-frame provided at the opposite ends thereof with wheel-guides having inclined grooved runways, and a pair of peripherally-grooved wheel-supporting rollers mounted in the base-frame between the opposite guides, said rollers being disposed in spaced parallel relation and in the same horizontal plane.

698,282. STEAM-PROPELLED ROAD-VEHICLE. STEVEN J. STRAIN, London, England. Filed Oct. 26, 1899. Serial No. 59,209. (No model.)

Claim.—In a steam-propelled road-vehicle, the combination with the front axle connected by springs to the frame so that it can rock and slide vertically, of a boiler arranged over the said axle, a shaft, a pair of horizontal engines in communication with the boiler and having their piston-rods connected to cranks at right angles to one another on said shaft, a pair of pinions of different diameters mounted on said shaft, a counter-shaft, a pair of wheels mounted on the counter-shaft and adapted to be suitably engaged by the said pinions, a sprocket-pinion mounted on said counter-shaft, a differential gear connecting the two parts of the hip axle of the vehicle, a sprocket-wheel on said gear, connections between said sprocket-pinion and said sprocket-wheel, springs attached to the frame of the vehicle and adapted to slide under it, bearings carried by the springs for the hip axle, a bearing on the counter-shaft, and a roller-rod for connecting the springs to the bearing on the counter-shaft.

698,283

698,283. RECTIFIER. WILLIAM T. THOMAS, Philadelphia, Pa. Filed Dec. 26, 1899. Serial No. 57,978. (No model.)

Claim.—1. In a rectifier, in combination, a cap having an aperture for branch wires for drop lights or the like, terminals carried on said cap, with which said branch wires are respectively in circuit, a base block having terminals adapted to make contact with the terminals of the cap plate, three grooves or channels formed in said base block and adapted to receive line wires, two of said grooves having contact devices adapted to make electrical connection with wires passing through said grooves, said contact devices being in circuit with the respective terminals of the base block.

2. In a rectifier, in combination, a cap having an aperture for branch wires for drop lights or the like, terminals carried on said cap, with which said branch wires are respectively in circuit, a base block having terminals adapted to make contact with the terminals of the cap plate, three grooves formed in said base block and adapted to receive three line wires (the central and one of the side grooves having each a contact device adapted to make electrical connection with a wire passing through the groove in which said contact device is situated, said contact devices being in circuit with the respective terminals of the base block.

3. In a rectifier, in combination, a cap having an aperture for branch wires for a drop light or the like, terminals carried on said cap with which said branch wires are respectively in circuit, a base block having terminals situated respectively on its opposite edge portions and adapted to make electrical connection with the terminals of the cap plate, three grooves or channels formed in said base block and adapted to receive three line wires, a contact device arranged in one of the side grooves and in circuit with one of the terminals of the base block, a second contact device located in the central groove, a conducting plate mounted on the rear portion of the block, and conducting connections uniting the contact device in the central groove, and the second of the terminals of the base plate, with said conducting plate, substantially as set forth.

698,284. AUTOMATIC FEEDING AND WINDING MECHANISM. FRANK C. WARD, New York, N. Y. Filed July 17, 1899. Serial No. 58,995. (No model.)

Claim.—1. The combination, with the feeding means, a stream-deflector, constructed and arranged to prevent accumulation of material behind the same when in non-feeding position, weighing mechanism, and means for operating the deflector to deflect the stream back to the feeding means, of a catch or detent for engaging the discharge portion of the weighing mechanism, a timed controlling device, means operated by the same for automatically releasing said catch, and a deflector-returning device actuated by the timed controlling device immediately after the release of the said catch and the return of the weighing mechanism to normal position, substantially as set forth.

2. The combination, with the feeding means, a stream-deflector constructed and arranged to prevent accumulation of material behind the same when in non-feeding position, and weighing mechanism, of means for locking the deflector in feeding position, means for automatically unlocking the same upon obtaining the predetermined weight, a catch for engaging the discharge portion of the weighing mechanism, a timed controlling device, means operated by the same for automatically releasing said catch, and a deflector-returning device actuated by the timed controlling device immediately after the release of the said catch and the return of the weighing mechanism to normal position, substantially as set forth.

3. The combination, with the feeding means, a stream-deflector constructed and arranged to prevent accumulation of material behind the same when in non-feeding position, weighing mechanism, and means for operating the deflector in one direction, of a catch for supporting the discharge portion of the weighing mechanism, a timed controlling device, means for changing the rate of speed of said controlling device, means operated by the timed controlling device for automatically releasing said catch, and a deflector-returning device independent of said catch and catch-releasing means, the same being actuated by the timed controlling device immediately after the release of said catch and the return of the weighing mechanism to normal position, substantially as set forth.

4. The combination, with weighing mechanism, of feeding means, a pivoted hanging deflector constructed and arranged to prevent accumulation of material behind the same when in non-feeding position, a counterweight for moving the deflector to material-returning position, and automatic means absolutely independent of the weighing mechanism for returning the deflector to material-feeding position immediately after the return of the weighing mechanism to normal position, substantially as set forth.

5. The combination with weighing mechanism, comprising a weighing-basket, adjustable in size, of a deflector adjustable in length relatively to the normal position of the weighing-basket, and means for feeding material, said deflector being arranged between the discharge portion of the feeding means and the weighing-basket, substantially as set forth.

6. The combination with suitable weighing mechanism, of means for feeding material, and a deflector adjustable in length and arranged in the space through which the material normally passes to the scale pan or basket of the weighing mechanism, substantially as set forth.

7. The combination, with weighing mechanism comprising a scale-beam and a suspended basket or weigh-box, of material-feeding means,

a movable deflector constructed and arranged to prevent accumulation of material behind the same when in non-feeding position, means, entirely dependent of any positive influence of but controlled by the weighing mechanism, for shifting said deflector to deflect, by one movement, the entire supply-stream from said basket and weighing mechanism being free from any retarding action of said shifting means, means for restraining the tendency of said shifting means and maintaining the deflector in full discharge position during the weighing, means suitably connected with the weighing mechanism for releasing the deflector from said deflector-restraining means, and means, independent of said shifting means and entirely independent of any influence of the weighing mechanism, for automatically and positively moving the deflector back to material-feeding position at regular predetermined intervals of time, substantially as set forth.

8. The combination, with weighing mechanism, of feeding means, a movable deflector constructed and arranged to prevent accumulation of material behind the same when in non-feeding position, means for positively locking the deflector in full material-feeding position, means for automatically releasing the deflector therefrom on obtaining the weight set, means for instantaneously shifting said deflector to full material-returning position, and means for positively and automatically moving the deflector back to locked position at regular and predetermined intervals of time immediately after the return of the weighing mechanism to normal position, substantially as set forth.

9. The combination, with power-driven mechanism, material-feeding means, and means for interrupting the feed of material, of weighing mechanism provided with a movable discharge portion, a catch engaging said discharge portion, a conveyor driven from said power-driven mechanism and onto which the material is dropped from the basket, an electromagnetic circuit, a circuit-closer, and a rotary tappet for striking the movable member of the circuit-closer, said tappet being timed relatively to the conveyor for causing it to close the circuit and thereby discharge said catch at the expiration of a predetermined period of time, substantially as set forth.

10. The combination with the feeding means, a gravitating deflector and weighing mechanism, of means for locking said deflector in feeding position, means for automatically unlocking the same, a source of electricity, an electromagnet, the armature of which is provided with a catch for engaging the discharge portion of the weighing mechanism, a circuit-closer, line connection between the source of electricity, magnet and circuit-closer, a timed controlling device for closing the circuit through said circuit-closer, and a deflector-returning device actuated by the timed device after the breaking of the circuit, substantially as set forth.

698,285. CRANE-LOADING APPARATUS. SAMUEL T. WILLIAMS, CHARLES E. WILLIAMS, JOHN W. SHAVER, and THOMAS R. HERRMAN, Cleveland, Ohio, assignors to the Williams Shaver Engineering Company, Cleveland, Ohio, a Corporation of Ohio. Filed Mar. 12, 1901. Serial No. 61,088. (No model.)

Claim.—1. The combination with a crane structure, of a trolley adapted to run thereon, depending and transversely-rigid lifting and supporting device carried by said trolley, a loading-pan, and supports to hold the pan in position under the crane structure, so that it can be engaged and lifted by the supporting and lifting device, substantially as described.

2. The combination of a travelling crane, a trolley thereon having transversely-rigid depending supporting and lifting device, a loading-pan, supporting means for fixedly supporting the pan in an inclined position under the lifting device, said lifting device adapted to lift the pan from its support and tilt it so as to dump its contents, substantially as described.

3. The combination of a crane with a trolley having transversely-

rigid depending hangers provided with means for engaging a pan, and means for operating one set of said hangers so as to raise the pan from its support, substantially as specified.

4. The combination of a crane with a trolley having transversely-rigid depending hangers provided with means for engaging a pan, and means for operating one set of said hangers so as to raise the pan from its support, and then tilt the same, substantially as specified.

5. The combination of a traveling crane with a trolley having depending hangers provided with means for engaging a pan, and electrically-controlled locking devices for said engaging means, substantially as specified.

6. The combination of a traveling crane, with a trolley having depending hangers for engaging a pan, the hangers for one end of the pan being rigid and those for the other end capable of being raised and lowered, substantially as specified.

7. The combination of a traveling crane, with a trolley having depending hangers for engaging a pan, one set of said hangers being rigid and the other comprising hoisting-tackle with telescopic movement, substantially as specified.

698,286. HYDRAULIC AIR-COMPRESSOR. JOSEPH WYMAN, Oultsburg, N. J. Filed Dec. 12, 1891. Serial No. 85,443. (No model.)

Claim.—1. The combination with a shell having water inlet and outlet openings a lever pivoted within the shell, two valves controlling the said openings and connected with said lever and a vertical rod connected at its lower end with the said lever and provided with vertically-sliding seats the lower seat having a limited upward movement on the rod to raise it, of air-delivery and air-vent in the upper end of the shell and a valve covering the air-vent raised by the direct action of the upper seat substantially as shown and described.

2. In a hydraulic air-compressor the combination with shell provided with water inlet and outlet openings a lever pivoted within the shell, valves attached to said lever and controlling said openings, a vertical rod pivotally connected at its lower end to said lever and seats movable up and down upon said rod of a valve-tube provided with air-delivery and air-vent, a nipple forming a continuation of the delivery-channel, a flexible apertured jacket covering the nipple, a valve controlling the air-vent, said valve having a hollow stem adapted to slide over the upper end of the seat-rod and capable of being operated by contact with the upper side of said seats substantially as shown and described.

3. In a hydraulic air-compressor a shell provided with water inlet and outlet openings, a lever pivoted within the shell, valves attached to said lever and controlling said openings, a vertical rod pivoted to one end of the valve-lever, and seats movable up and down upon said rod in combination with a valve-tube provided with air-delivery and air-vent a nipple forming a continuation of the delivery-channel, a flexible apertured jacket covering the nipple a hinged cap surrounding and a valve controlling the air-vent with a hollow stem adapted to slide over the seat-rod and capable of closing the delivery-outlet by contact with the upper end of said seats substantially as shown and described.

698,287. ELECTRIC VAPOR-LIGHTER. BURTUS E. WILSON, Chicago, Ill. Filed Dec. 20, 1891. Serial No. 85,673. (No model.)

Claim.—1. A lighting device, comprising a fluid-reservoir, a sheath tube, means for supporting said reservoir and tube in their proper relative position, a torch removably telescoped in the sheath-tube, means for supplying the fluid contents of the reservoir to the sheath-tube in a usable quantity, and the electric connections for automatically igniting the torch as it is being withdrawn from its normal position, substantially as set forth.

2. In a lighting device of the kind described, the combination with a fluid-reservoir, of a torch sheath-tube, the capillary conductor connecting the reservoir and sheath-tube, the torch-tube adapted to be removably

inserted in the sheath-tube, the torch-wire held normally out of contact with the torch-tube but momentarily engaging the same on its outward movement, the companion torch-wire, and means for bringing the sparking end thereof in contact with the torch and close the circuit; substantially as set forth.

3. In a lighting device of the kind described, the combination with a sheath-tube, having a saturated inflammable substance in the closed end thereof and provided with openings adjacent to its outer end, of a torch-tube, having an ignitable end and adapted to be removably inserted in the sheath-tube, and means for automatically lighting the torch each time that it is withdrawn from its normal position substantially as set forth.

4. In a lighting device of the kind described, the combination with a sheath-tube having a beveled shoulder and secured in a stationary position, of a lighting-torch, provided near its inner end with an annular groove and having a removable telescopic engagement with the sheath-tube, a hinge part, the positive circuit-wire having an insulated connection with the movable member of said hinge and extending therefrom to and around the sheath-tube in position to engage the annular groove in the torch when the latter is partly withdrawn, the negative circuit-wire secured to and moving with the movable member of the hinge part in closing the circuit and igniting the torch, and means for releasing the positive wire from its engagement with the torch at the proper time, substantially as set forth.

5. In a lighting device of the kind described, the combination with a fluid-reservoir, of a sheath-tube, secured in a stationary position, a wick-tube having one end inserted in the reservoir and the other end opening into the closed end of the sheath-tube, the capillary conductor running through the wick-tube, a torch removably extending into the closed bottom end of the sheath-tube, the electric connections, and means for closing the circuit in lighting the torch by the action of withdrawing the same, substantially as set forth.

6. A lighting device of the kind described, comprising a tank plate, a fluid-reservoir, a sheath-tube, a tube and wick conducting the fluid contents of the reservoir into the closed bottom end of the sheath-tube, a lighting-torch, removably inserted in the sheath-tube, the insulating case, the electric circuit connections and means actuated by the withdrawal of the lighting-torch in closing and breaking the circuit at the proper time, substantially as set forth.

698,288. SKIRT-PROTECTOR. WILLIAM F. WYMAN, Schuylkill, Wis., assignor to Aaron H. Weber, Schuylkill, Wis. Filed Nov. 9, 1890. Serial No. 736,308. (No specimens.)

Claim.—1. A skirt-facing goods consisting of a strip turned over on itself and stitched at the fold through both thicknesses to form a ridge, the free edge being turned over to enclose the ridge and attached to the body of the strip.

2. A skirt-folding goods including a strip provided with a ridge in its body portion, the free edge beyond the ridge being folded over said ridge and secured to the body of the strip.

3. A skirt-folding goods including a strip turned over on itself and stitched at the fold through both thicknesses to form a ridge, the free edge being turned over and stitched to the body of the strip to imitate the ridge, and a cord-stitch in said ridge.

698,989. TRAMWAY-SWITCH. JOHN E. V. VORSE and RALPH W. RANK, Akron, Ohio. Filed May 29, 1901. Serial No. 62,371. (No model.)

Claim.—1. The combination with track-rails and a switch-tongue, of a trip-head adapted to be actuated by the wheels of a passing vehicle, a horizontally-movable pivoted lever for shifting said switch-tongue, a vertically-movable pin carried by the free end of said lever, an angular lever hinged to the trip-head and provided with a laterally-extending head to receive the lower end of the trip-pin, whereby when said trip-head is depressed, the trip-pin will be elevated to be within the path of movement of suitable mechanism carried by the vehicle for shifting said switch-tongue, substantially as set forth.

2. The combination with the track-rails and the switch-tongue, of a trip-head adapted to be actuated by the wheels of a passing vehicle, a horizontally-movable pivoted lever having an aperture in one end, a stud depending from the switch-tongue, a link pivotally connecting one end of said lever to the said stud, a pin mounted to slide vertically in the aperture at the opposite end of said lever, and an angular lever hinged to the trip-head and provided with a laterally-extending head to receive the lower end of the trip-pin, whereby when said trip-head is depressed, the trip-pin will be elevated to be within the path of movement of suitable mechanism carried by the vehicle for shifting said switch-tongue.

698,940. PROCESS OF AGING AND BLEACHING FLOUR. JOHN ARTHUR and SYDNEY ARTHUR, Belfast, Ireland. Filed Feb. 6, 1901. Serial No. 48,138. (No specimens.)

Claim.—1. The improvement in the process of aging and bleaching flour, which consists in passing chemically inactive gaseous material

through a liquid existing medium capable of being slowly volatilized by said inactive gaseous material, and bringing the resulting gaseous mixture into intimate contact with the flour, substantially as described.

2. The improvement in the process of aging and bleaching flour, which consists in passing the same in a state of fine division through an atmosphere containing a small regulated quantity of gaseous nitric acid.

3. The improvement in the process of aging and bleaching flour, which consists in bringing air into contact with nitric acid, whereby it takes up a minute quantity of the latter, and bringing this gaseous mixture into intimate contact with the flour, substantially as described.

698,941. NON-REFILLABLE BOTTLE. THOMAS E. RALSTON, Elizabeth, N. J. Filed Sept. 11, 1901. Serial No. 78,061. (No model.)

Claim.—1. A bottle having a neck, a disk of penetrable material cut into said neck when the bottle is formed and before it is filled, the neck being left unobstructed below the disk, and sealing material covering the disk, said material being applied after the bottle is filled.

2. A bottle having a neck, an asbestos diaphragm cut into the neck when the bottle is formed and before it is filled, the neck being unobstructed below the diaphragm so that the bottle may be filled through the latter, an inward curvature in the neck above the diaphragm, and sealing material between the diaphragm and curvature, for the purpose specified.

3. A bottle having a neck, a thin diaphragm of asbestos having a strengthening-rim on its outer edge cut into the neck when the bottle is formed and before it is filled, means for filling the bottle with the diaphragm in position, and means for sealing over the diaphragm to close the bottle.

698,942. DRILLING-MACHINE. SAMUEL J. BAKER, Springfield, Vt. Filed Aug. 17, 1901. Serial No. 72,200. (No model.)

Claim.—1. In a drilling-machine, the frame comprising a base-plate, a hollow column secured thereto, and a second hollow column telescopically arranged with reference to the first, a suitably-actuated main shaft located within the hollow column, and a screw-threaded shaft similarly located and in engagement with the upper column, together with means for gearing the screw-threaded shaft to the main shaft.

2. In a drilling-machine, the combination with the frame comprising a base, a hollow column secured thereto and a second hollow column telescopically arranged with respect to the first, and provided with means for raising and lowering it, of a main shaft located within the two hollow columns, stepped at its lower end in said base, passing through the upper end of the upper sliding column and there provided with a tapered transmitting-gear, and means for rotating the main shaft, substantially as described.

3. The combination with the cylindrical casing or holder, having an opening at one side, and feed-gearing exterior to the casing or holder with one of its gears at said opening, of a cylindrical turret mounted in said casing and provided therethrough with a circularly-arranged series of longitudinal bores, each opening laterally out through the outer side of the turret to register with the single opening in the casing, a series of spindles extending through said bores and provided adjacent to the side openings thereof with feed-nuts, adapted to be engaged by the feed-gear at the casing-opening, driving-gears splined to the spindles at the top of the turret, driving-gearing with which any of the spindle-gears may mesh for continuous rotation and means for normally holding the spindles raised; substantially as described.

4. A drilling-machine comprising a telescopic column or standard, a main drive-shaft extending up through the standard and provided with a transmitting-gear splined thereon above the upper member of the column, a cylindrical turret holder or casing mounted on the said upper column member and provided with a lateral opening through one side, feed-gearing mounted on the turret-holder with one of its gears adjacent to said opening, a cylindrical turret mounted in said holder and having a series of lateral openings leading from said bore to register with the opening in the turret-holder, spring-actuated spindles in the said bore, feed-racks mounted loosely on the spindles within said bore and exposed through the lateral openings for operation by the said feed-gearing when brought into register therewith; substantially as described.

5. The combination with the cylindrical turret-holder having an opening through one side, feed-gearing mounted adjacent to said opening, a cylindrical turret mounted in the holder, and having a circularly-arranged series of bore, each having a lateral opening to register with the opening in the turret-holder, a series of spindles mounted in said bore and having feed-racks at the lateral openings for engagement with said feed-gear when brought into register therewith, drive-gears splined on the spindles at the top of the turret, a main drive-shaft, a common driving-gear mounted on top of the holder for engagement with any one of the spindles-gears, and gearing mounted on the holder and connecting said common driving-gear to the main drive-shaft; substantially as described.

6. A turret-drill comprising, a cylindrical holder or casing, a cylindrical turret mounted to turn therein, and provided with a series of drill-spindles extending through it and each provided at the top of the turret with a splined drive-gear, feed-gearing mounted at the side of the turret-holder and adapted to engage each spindle to feed the same when brought into register therewith, a common drive-gear mounted on top of the holder for operating the spindles as their drive-gears are brought into mesh therewith, a main drive-shaft, gearing connecting said main shaft with said common gear, a vertically-disposed feed-operating shaft also geared at its upper end to said common gear, means for operatively connecting the lower end of the vertical shaft to said feed-gearing for driving the same automatically and means for operating the feed-gearing by hand; substantially as described.

7. The rotatable turret, a series of spindles mounted therein, each of the said spindles having a rack connected thereto, and means for imparting rotary motion to any selected spindle, in combination with a movable box carrying a pinion for engagement with the rack and also a worm-gear geared to the pinion, together with a worm mounted so as to engage with the worm-gear when the box is in its operative position, and means for operating the worm.

8. The rotatable turret, a series of spindles mounted therein, each of said spindles having a rack connected thereto, and means for imparting

rotary motion to any selected spindle, in combination with a movable box carrying a pinion for engagement with the rack and also gearing connected to the said pinion, together with means for manually operating the said gearing when the box is in its operative position.

9. The rotatable turret, a series of spindles mounted therein, each of the said spindles having a rack connected thereto, and means for imparting rotary motion to any selected spindle, in combination with a movable box carrying a pinion for engagement with the rack and also a worm-gear geared to the pinion, together with a worm mounted so as to engage with the worm-gear when the box is in its operative position, and means for operating the worm.

10. The rotatable turret, a series of spindles mounted therein, each of the said spindles having a rack connected thereto, and means for imparting rotary motion to the selected spindle, in combination with a movable box, a pinion carried thereby for engagement with the rack, and a worm-gear also carried in the box and geared to the pinion, together with a pivoted bracket, and a rotatably-actuated worm mounted in said bracket whereby the worm may be caused to engage the worm-gear when the movable box is in its operative position.

11. In a drilling-machine, the combination with a spindle, of means comprising a tubular worm which may be manually operated for feeding the spindle, together with a constantly-actuated shaft passing freely through the worm and normally not connected thereto, but provided with a clutch whereby the manual feed of the spindle may be changed to an automatic feed.

12. In a drilling-machine, the combination with a spindle and its feed-gearing, of a tubular worm for operating said gearing, a hand-wheel connected to said worm and provided at one side with a clutch-connection, a constantly-actuated shaft passing through the worm and provided with a clutch member at one end and means for engaging the clutch member with that on the hand-wheel; substantially as described.

13. In a drilling-machine, the combination of a spindle, and means for imparting a rotary motion thereto, with gearing mounted in a movable box for imparting an automatic feed to the spindle, an actuating member normally engaging the said gearing when the box is in its operative position, a pivoted bracket carrying the said member, and a catch for maintaining the bracket in position, a rod connected to the catch, a spring pressing upon the rod, and a pivoted lever attached at the other end of the rod, together with a stop attached to the spindle whereby in the descent of the spindle the bracket and member carried thereby may be released from operative position.

698,243. STRAIN NET-WORKS FOR SAWMILLS. ROBERT F. BARKER and HENRY CURRY, Martinsburg, W. Va. Filed June 24, 1901. Serial No. 66,993. (No model.)

Claim.—1. In a sawmill net-work, in combination, an engine, a pair of intermeshing roller-shafts, means for imparting motion from the engine to the roller-shafts, a set-shaft, a pair of co-acting ratchet-wheels driven from the roller-shafts, a circular pawl-carrier concentric with each of the ratchet-wheels, and a plurality of pawls mounted upon each of the carriers and engaging the companion ratchet-wheel.

2. In a sawmill net-work, in combination, an engine, a pair of intermeshing roller-shafts, a set-shaft, a ratchet-wheel, a clutch for coupling the ratchet-wheel with the set-shaft, a pair of oppositely-driven pawl-carriers, and pawls mounted on the carriers and engaging the ratchet-wheel.

3. In a sawmill net-work, in combination, a set-shaft, a pair of co-acting roller-shafts, an engine, gearing for imparting motion from the engine to the roller-shafts, and pawl-and-ratchet mechanism for communicating motion to the set-shaft.

4. In a sawmill net-work, in combination, an engine, a pair of in-

termeshing roller-shafts, rack-and-pinion connection between the engine and one of the shafts, a set-shaft, a ratchet-wheel mounted thereon, two sets of pawls engaging the ratchet-wheel, and operative connection between each roller-shaft and one set of the pawls.

5. In a sawmill net-work, in combination, a set-shaft, a pair of roller-shafts, a segmental gear fixed on one of said shafts, a rack-bar for driving the segmental gear, means for reciprocating the rack-bar, a segment fixed to the other shaft and driven by the segmental gear whereby the said shafts are rotated in opposite directions, a pair of pawl-carriers, connection between the pawl-carriers and the roller-shafts, a ratchet-wheel for communicating motion to the set-shaft, and pawls mounted on the carriers and engaging the ratchet-wheel.

6. In a sawmill net-work, in combination, an engine, a set-shaft, means for transmitting motion from the engine to the set-shaft, and a step-block pivoted in the path of a moving part of the engine and which is provided with a plurality of adjustable abutments.

7. In a sawmill net-work, in combination, an engine, a set-shaft, connection between the engine and the set-shaft, a pivoted step-block for the engine, and a plurality of radially-adjustable abutments projecting from the face of the block.

8. In a sawmill net-work, in combination, a reciprocating engine, a cross-head carried by the piston thereof, a set-shaft, means for transmitting motion from the engine to the set-shaft, a pivoted cam-shaped step-block provided with a series of steps and engaging between the path of the cross-head, and an adjustable abutment located on each step.

9. In a sawmill net-work, in combination, an engine, a pair of intermeshing co-acting roller-shafts, connection between the engine and one of the shafts, a set-shaft, and pawl-and-ratchet mechanism for driving the set-shaft intermittently forward.

10. In a sawmill net-work, in combination, an engine, a pair of intermeshing co-acting roller-shafts, connection between the engine and one of the shafts, a set-shaft, a pawl-and-ratchet mechanism actuated by the roller-shafts for driving the set-shaft intermittently forward, and a clutch for coupling the pawl-and-ratchet mechanism with the set-shaft.

11. In a sawmill net-work, in combination, a set-shaft, an engine, a pair of intermeshing co-acting roller-shafts, means for imparting motion from the engine to the roller-shafts, a pair of pawl-carriers, connection between the pawl-carriers and the roller-shafts, a ratchet-wheel for communicating motion to the set-shaft, and pawls mounted on the carriers and engaging the ratchet-wheel.

12. In a sawmill net-work, in combination, a set-shaft, a pair of co-acting roller-shafts, an engine, means for imparting motion from the engine to the roller-shafts, and pawl-and-ratchet connection between the roller-shafts and the set-shaft.

13. In a sawmill net-work, in combination, an engine, a set-shaft, means for transmitting motion from the engine to the set-shaft, a step-block pivoted in the path of a moving part of the engine and the face of which is concentric to its pivot, a plurality of radially-adjustable abutments projecting from the face of the step-block, and means for rotating the speed of the engine.

698,244. COMPENSATION OF GENERATORS OR MOTORS. FRANK S. BAIN, Stamford University, Cal., assignor to Stanley Electric Manufacturing Company, Pittsfield, Mass., a Corporation of New Jersey. Filed Aug. 20, 1901. Serial No. 73,515. (No model.)

Claim.—1. In a system of distribution the combination of an alternating-current generator, an exciter therefor, a compensator energized by the alternating current in the main-generator circuit leading to the translating device and energizing in part the field-magnet of the exciter.

2. In a system of distribution the combination of an alternating-current generator, an exciter therefor, and a compensator energized by the alternating current in the main-generator circuit leading to the translating device, said compensator being in series with the armature and field-coil of the exciter.

3. In a system of distribution by alternating currents, a compensator consisting of a field-magnet energized by the alternating current in the main leading to the translating device, an armature rotating relatively thereto, synchronously with the main generator and a rectifying-commutator, said compensator supplying current to the field-magnet of an exciter for the main generator.

4. In a system of distribution by alternating currents, a compensator consisting of a field-magnet energized by alternating currents in the main leading from the main generator to the translating device, an armature rotating relatively thereto, synchronously with the main generator and a rectifying-commutator, having the conducting-segments corresponding to one-half of each period removed.

5. In a system of distribution by alternating currents, a compensator consisting of a field-magnet energized by the alternating current in the main leading to the translating device, an armature rotating relatively

thereto, synchronously with the main generator and a rectifying-commutator, having the conducting-segments corresponding to one-half of each period and means for automatically changing the brushes thereof when they are not upon the conducting-segments of the commutator.

698,245. MEANS FOR COMPENSATING GENERATORS OR MOTORS. FRANK S. BAIN, Stamford University, Cal., assignor to Stanley Electric Manufacturing Company, Pittsfield, Mass., a Corporation of New Jersey. Filed Sept. 5, 1901. Serial No. 74,574. (No model.)

Claim.—1. In a system of distribution, the combination of a plurality of dynamo-electric machines having but one energizing-winding on each of their field-magnets, and an auxiliary dynamo-electric machine in series with the field-magnet windings and having an energizing-coil in series with the armature-circuits of the main dynamo-electric machines.

2. In a system of distribution, the combination of a plurality of generators in multiple are having their energizing-coils in multiple are and an auxiliary generator having a field-magnet coil in series with the load on the system and supplying energy to the energizing-coils of the main generators.

698,246. APPARATUS FOR ROASTING COFFEE. ROBERT BENTLEY, London, England. Filed July 22, 1901. Serial No. 68,315. (No model.)

Claim.—1. In an apparatus for roasting, drying and similar purposes the combination with a rotatable chamber of a heated belt removably arranged within the chamber and a perforated casing enclosing the belt so as to form the purpose specified.

2. In an apparatus for roasting, drying and similar purposes the combination with a chamber of a removable heating-belt disposed within the chamber, a perforated casing placed between the belt and the material under treatment, a door in the chamber and means for rotating the apparatus.

3. In an apparatus for roasting, drying and similar purposes, the combination with a chamber of a heated belt disposed within the chamber, a perforated casing between the belt and the material under treatment, a door in the chamber, a hollow extension on one end of the chamber for the reception of the belt and an inwardly-extending projection on the other end of the chamber to support the belt substantially as described.

4. In an apparatus for roasting, drying and similar purposes the combination with a chamber of a heated belt disposed within the chamber, a

perforated casing between the belt and the material under treatment, a door in the chamber, a hollow journal on one end of the chamber for the reception of the belt, an inwardly-extending projection on the other end of the chamber to support the belt and a radial arm within the chamber substantially as and for the purpose described.

5. In an apparatus for roasting, drying and similar purposes the combination with a chamber of a heated belt disposed therein, a perforated casing placed between the belt and the material under treatment, a radial arm on the inner casing, a door in the outer casing and means for rotating the chamber.

698,247. **PARTNER FOR KIDS OF CORD**, Dr. **MOORE BARNARD** and **RAYMOND T. VINE**, Buffalo, N. Y. Filed Dec. 27, 1901. Serial No. 57,468. (No model.)

Claim.—A clip for temporarily binding the end of a round cord, consisting of a narrow strip of flexible, non-resilient material adapted to be bent in approximately U form around the cord, crosswise of its strands, and having its ends pointed and bent inwardly toward the crotch of the clip for penetrating the strands of the cord and provided between its pointed ends and its crotch with inwardly-projecting barbs arranged to penetrate opposite sides of the cord substantially as set forth.

698,248. **MAST-FURNACE**, **EMIL BERNHARD**, Kladno, Austria-Hungary, assignor to the **Wellman-Sever Engineering Company**, Cleveland, Ohio, a Corporation of Ohio. Filed May 1, 1900. Serial No. 714,598. (No model.)

Claim.—1. A blast-furnace having a feed bell or cone and a vertically-movable hopper above the cone, said hopper having a normally closed top and being provided with an external coil whereby its vertical movement is permitted without causing escape of gas.

2. A blast-furnace having a hopper with a valve in the top of the cone, a feeding-bogie, and supports therefor in combination with a single means for successively raising said valve and discharging the contents of said feed-bogie.

3. A blast-furnace having a feed-hopper with a vertically-movable valve in the top of the cone, a feed-bogie, supports therefor, a shell or mantle on said bogie, and a lifting bar or frame connected to the hopper-valve and having portions for engaging and lifting the shell of the feed-bogie after the valve has been lifted to a certain extent.

4. A blast-furnace having at its upper portion an outer gas-discharge chamber, a central hollow gas-receiving chamber and hollow arms open at the bottom and connecting said central gas-receiving chamber with the outer gas-chamber whereby the gases can escape both through the central chamber and through the hollow arms.

5. A blast-furnace having at the top a feed bell or cone and below the cone a central structure with radiating arms extending downwardly beyond said feed-bell, and curved arm-plates for protecting said depending portions of the arms.

6. A blast-furnace having at the top an outer gas-discharge chamber and a central gas-chamber, hollow arms providing communication between said central gas-chamber and outer gas-chamber, and passages lead-

ing from the combustion-chamber of the furnace into the outer gas-chamber independently of said arms.

7. A blast-furnace having at the upper portion a discharge-chamber, hollow arms communicating therewith and extending inwardly into the upper portion of the furnace, said hollow arms being open at the bottom throughout their extent so as to receive gas from the material in the furnace.

8. A blast-furnace having a stationary feed-bell in the upper portion, a central gas-collecting chamber below said feed-bell, and terminating in the upper portion of the furnace, an outer gas-discharge chamber and hollow arms leading from said central gas-collecting chamber to the outer discharge-chamber.

698,249. **SHOULDER**, **EDWIN R. BARNARD**, Chicago, Ill. Filed June 27, 1901. Serial No. 51,517. (No model.)

Claim.—1. In a bolted, in combination, a pillar, a side rail, a hook formed on the rail for engaging the pillar, a clamping member pivoted to the rail for engaging the pillar in opposition to the hook, a draw-bolt pivotedly secured to the rail between the end thereof and the point of attachment of the clamping member, and a nut running on the bolt for bearing upon the back of the clamping member.

2. In a bolted, in combination, a pillar, a side rail, a hook formed on the rail for engaging the pillar, a clamping member pivoted to the rail for engaging the pillar in opposition to the hook and having its cheek slotted, a draw-bolt pivotedly secured to the rail between the end thereof and the point of attachment of the clamping member and passing through the slot of the clamping member, and a nut on the outer end of the bolt.

3. In a bolted, in combination, a pillar, a side rail, a hook formed on the rail for engaging the pillar, a clamping member pivoted to the rail for engaging the pillar in opposition to the hook, a draw member pivoted to the side rail intermediate of its end and the pivot of the clamping member, and a threaded part coacting with the draw member to force the clamping member to the pillar.

4. In a metal bedstead, in combination, an end frame having pillars and a cross-rail, a block forming the means of attachment of the cross-rail to the pillar, each block controlling the post and having its upper edge scalloped or corrugated, a side rail, a hook attached to the side rail for engaging the pillar and having its edge scalloped or corrugated to correspond with the scallops or corrugations of the block, and means for clamping the hook to the rail.

698,250. **RAIL-ROAD**, **GEORGE R. BARNARD**, Tacoma, Wash. Filed Jan. 12, 1902. Serial No. 50,694. (No model.)

Claim.—1. A rail-head consisting of a laminated strip formed to present a pair of flat feet and an extendible intermediate portion, and composed of a number of superimposed independent strips, the end portions of all of which are completely coated with solder, one of the outside strips being made longer than the other strips having its end portions turned up over and upon the other end portions, and a ribbon of solder attached to one side of each flat foot, substantially as described.

2. A rail-head consisting of a laminated strip formed to present a pair of flat feet and an extendible intermediate portion and a ribbon of solder attached at one end to one side of each flat foot, substantially as described.

698,251. **CROSS-ROAD FOR RAILS**, **GEORGE R. BARNARD**, Tacoma, Wash. Filed Jan. 30, 1902. Serial No. 51,508. (No model.)

Claim.—1. A cross-road consisting of a cross-wire and a laterally-projecting strip attached thereto at both ends, substantially as described.

2. A cross-road consisting of a cross-wire, and a laminated strip attached thereto at both ends, substantially as described.

3. A cross-road consisting of a cross-wire having a laminated strip attached thereto at both ends and projecting laterally therefrom, substantially as described.

4. A cross-road consisting of a cross-wire having a laminated strip attached thereto at both ends and provided at its extremity with a flat foot, substantially as described.

5. A cross-road consisting of a cross-wire having a laminated strip attached thereto at both ends and projecting laterally therefrom and provided with an extendible intermediate portion, substantially as described.

698,252. **HYDRO-LEAF TURNER**, **ABRAHAM BERNHARD**, Utrecht, Netherlands. Filed Jan. 3, 1902. Serial No. 51,507. (No model.)

Claim.—In a waste-leaf turner the combination of a supporting frame, a vertically-adjustable rest for the waste-leaves, spring-actuated leaf-turning arms pivoted at the top of the frame and adjustable to the length of the leaves, clamps at the free ends of said arms for attaching said leaves, spring-actuated hook-levers for securing said arms in position when turned over against the action of their spring, a vertically-movable upwardly-spring-pressed rack-bar guided on the rear side of said frame, a horizontal arm at the top of said rack-bar engaging the free ends of said hook-levers for releasing the turning-arms when moved downwardly, a projection at the front of said rack for actuating said horizontal arm in releasing the turning-arms by pressing them downwardly free from the rack, a piston working with said rack-bar, a ratchet connected to said piston, a pawl engaging said ratchet, an upwardly-spring-pressed arm pivoted to the frame and carrying said pawl, a catch on said rack-bar, a

projection on said frame engaging said catch for moving the rack-bar in position when operated, two finger-pieces respectively pivoted to the right and left corners of the frame and two sets of levers each transmitting the limited motion of one operated finger-piece to the pawl, ratchet piston and rack for the purpose of releasing the leaf-turning arms one by one, substantially as described.

698,253. **MACHINE FOR MOVING BOULDERS**, Dr. **PETER BOUQUET**, Waterville, Cal. Filed Feb. 4, 1901. Serial No. 45,086. (No model.)

Claim.—1. The combination of the shaft or handle-bar A and arms or claws B B with upward notched-teeth C C C on their forward surfaces, and spillo D, and hook E, all substantially as shown and described.

2. The form and combination of the shaft or handle-bar A and arms or claws B B with upward notched-teeth C C C on their forward surfaces and spillo D, and hook E, for the use and purpose of moving rocks, boulders and other heavy compact substances, substantially as shown and described.

698,254. **METHOD OF OBTAINING THERAPEUTIC FROM CELLULOSE SOLUTIONS**, **ERNEST BARNARD**, Rochester, N. Y., and **MAX FREEMAN** and **JEROME URBAN**, Ansonia, Conn. Filed Apr. 22, 1901. Serial No. 50,695. (No specimens.)

Claim.—1. A method of obtaining therapeutics from solutions of cellulose by expressing the cellulose solution into sulfuric-acid solution containing from thirty to sixty-five per cent. of real acid.

2. A thread produced from a cellulose solution expressed into a sulfuric-acid solution containing from thirty to sixty-five per cent. of real acid.

698,255. ART OF COLOR-PRINTING. CLARENCE P. BROWNE, Washburn, N. Y. Filed Oct. 26, 1901. Serial No. 12,147. (No model.)

Claim.—1. A plate for printing having annular walls formed thereon as guides for drilling registry-holes, the center space or well formed by said walls being of the diameter of the drill used in boring the registry-holes.

2. A series of plates for color-printing, each of which plates has annular walls formed thereon during the production of the plate as set forth and in identical positions on the remaining plates of the series, said walls forming walls to receive and guide the drill used in boring the registry-holes.

3. The combination with a bed for printing-presses having ways formed in the surface thereof, of registry-pins mounted in the ways and adjustable to different places on the surface of the bed, for the purpose set forth.

4. A bed for printing-presses having slots or channels formed therein and slides adjustable longitudinally in said channels and registry-pins mounted in said slides as set forth for the purpose set forth.

5. A bed for printing-presses having channels formed therein, slides fitted to said channels, registry-pins carried by said slides, and means for fixing the slides in adjusted position.

6. A bed for printing-presses having undercut channels formed therein with narrow openings in the face of the bed, slides fitted to said channels and fitting-shims flush with the surface of the bed, pins carried by said slides and projecting above the surface of the bed.

7. A bed for printing-presses for use in color-printing having slots formed radially therein, slides adjustable longitudinally in said slots and registry-pins carried on the inner ends of said slides.

8. A supplemental bed for use in color-printing having slots formed radially therein, slides adjustable longitudinally in said slots, registry-pins for a plate in one pair of opposing slides, and pins for sheet-registry in another pair of opposing slides, substantially as set forth.

698,256. ILLUMINATED SIGN. GUY D. CHAPMAN AND CLYDE R. GUNN, Akron, Ohio. Filed Jan. 20, 1902. Serial No. 91,996. (No model.)

Claim.—1. The combination in a letter for signs, of a body portion, and depending sockets for the reception of incandescent electric lights made integral with said body portion.

2. The combination in a letter for signs of a non-conducting body portion provided on its outer face with a groove and depending sockets for the reception of incandescent electric lamps made integral with said body portion.

3. The combination in a letter for signs, of a main body portion, and extended sockets for incandescent electric lamps integral with said main body portion, said sockets being smaller in diameter at the place of junction with said main body portion.

698,257. SOLE LAYING AND BOUNDING MACHINE. WALTER H. CLARK, North Marshfield, Mass. Filed Nov. 26, 1900. Serial No. 12,148. (No model.)

Claim.—1. In a machine of the class described, a yieldingly-mounted jack to support a luted shoe, a rigidly-mounted former, said former having a contour substantially the same as the sole of a shoe, and having one face shaped to fit the bottom of the last, and means to move one of said parts relative to the other, whereby the sole may be molded between the luted shoe and former, combined with sole-rounding mechanism to round the sole while clamped between the former and luted shoe.

2. In a machine of the class described, a yieldingly-mounted jack to support a luted shoe, a rigidly-mounted former having one face shaped to fit the bottom of the last, means to move the jack to bring the last in

contact with the former, means to subsequently move the former against the luted shoe on the yielding jack, whereby a sole placed between the former and luted shoe may be molded to the shape of the last combined with sole-rounding mechanism to round the sole while clamped between the former and the shoe.

3. In a machine of the class described, a yieldingly-mounted jack to hold a last, a support, a former rigidly carried thereby, means to clamp a sole-blank between the shoe on the last and the former, the said former being detachably mounted on the support, whereby either right or left soles may be molded and laid.

4. In a machine of the class described, a yieldingly-mounted jack to hold the last, a support, a former rigidly carried thereby but detachably therefrom, whereby either right or left formers may be used, said formers having one face shaped to fit the bottom of the last, means to move the jack to bring the last in contact with the former, and means to subsequently move the former against the last and the yielding jack, whereby a sole placed between the former and last may be molded to the shape of the last.

5. In a machine of the class described, a cross-head, guideways therefor, a jack yieldingly carried by said cross-head and adapted to support a last, a former, means to lower the cross-head to bring the shoe on the last in contact with the former, means to lock the cross-head in its lowered position, and means to raise the former against the last on the yielding jack, whereby a sole may be molded between the former and shoe, and at the same time attached to the shoe.

6. In a machine of the class described, a yieldingly-mounted jack to hold a last, a rigidly-mounted former having one face shaped to fit the bottom of the last, means for forcing the former against the last, said means including a shaft, an eccentric thereon, connections between the eccentric and former, clutch mechanism to rotate the shaft and means to automatically disengage said clutch mechanism, when the former has reached the upward limit of its movement.

7. In a machine of the class described, a non-rotatable jack to support a last, a former having one face adapted to fit the bottom of the last, means to clamp a sole-blank between said former and last, and sole-rounding mechanism to round the sole while between the former and last, rounding mechanism including a knife mounted for turning-movement.

8. In a machine of the class described, a non-rotatable yieldingly-mounted jack to support a last, a former having one face adapted to fit the bottom of the last, means to clamp a sole-blank between said former and last, and sole-rounding mechanism to round the sole while between the former and last.

9. In a machine of the class described, a jack adapted to support a luted shoe, a former, means to clamp a sole-blank between the former and luted shoe, and sole-rounding mechanism, said mechanism being guided by the last, and having a knife supported for turning movement.

10. In a machine of the class described, a jack to support a last, a former, means to clamp a sole between the former and last, a cutting mechanism, means to carry the same around the shoe, and means controlled by the last for guiding said cutting mechanism whereby the sole is rounded to the shape of the last.

11. In a machine of the class described, a jack to support a last

shoe, a former, means to clamp sole-blanks between the former and last, a carriage supporting a knife, means to propel the carriage around the sole, and means controlled by the last to guide the knife, whereby the sole is rounded to the shape of the last.

12. In a machine of the class described, a jack to support a luted shoe, a former, means to clamp sole-blanks between the former and last, a carriage supporting a knife, means to propel the carriage around the sole, and means controlled by the last to guide the knife, the said knife having a turning movement relative to the carriage.

13. In a machine of the class described, a jack to support a last, a former, a carriage, a guideway therefor extending around the shoe, a slide on the carriage, a knife on said slide, and means controlled by the last to guide the knife.

14. In a machine of the class described, a jack forming a support for the last, a former, means to clamp a sole-blank between the last and former, a carriage, a slide carried thereby and supporting a knife, a guide on the slide adapted to contact with the shoe on the last, means to propel the carriage around the shoe, whereby the knife rounds the sole to the shape of the last.

15. In a machine of the class described, a jack, forming a support for the last, a former, means for clamping a sole-blank between the former and shoe on the last, a carriage, a slide carried thereby and supporting a knife, a guide on the slide, means to propel the carriage around the shoe, and means to maintain the contact of the guide with the shoe on the last, whereby the knife rounds the sole to the shape of the last.

16. In a machine of the class described, a jack forming a support for the last, a former, means for clamping a sole-blank between the former and shoe on the last, a carriage, a slide carried thereby, a knife supported for turning movement on the slide, means to propel the carriage around the shoe, and means to maintain the contact of the guide with the shoe on the last, whereby the sole is rounded to the shape of the last.

17. In a machine of the class described, a jack to support a last, a former having one face shaped to fit the bottom of the last, means to clamp and mold a sole-blank between the former and the shoe on the last, a carriage, a slide mounted thereon for movement at right angles to the direction of movement of the carriage, a knife on the slide, means to propel the carriage around the shoe, and means controlled by the last to guide the knife, whereby the sole is rounded to the shape of the last.

18. In a machine of the class described, a jack to support a last, a former having one face shaped to fit the bottom of the last, means to clamp and mold a sole-blank between the former and the shoe on the last, a carriage, a guideway therefor extending around the shoe, a slide mounted on the carriage for movement at right angles to the direction of movement of the carriage, said slide carrying a support for the under side of the sole, and a knife for rounding the sole, means to propel the carriage around the shoe, and means governed by the last controlling the movement of the slide, whereby the sole is rounded to the shape of the last.

19. In a machine of the class described, a jack to support a last, a former, means to clamp and mold a sole-blank between the former and shoe on the last, a carriage, a guideway therefor, a slide on the carriage, and means for movement at right angles to the direction of movement of the carriage, said slide carrying a sole-rounding knife and a guide-wheel adapted to contact with the shoe on the last, means to propel the carriage around the shoe, and means to preserve the contact of the guide-wheel with the shoe, whereby the sole is rounded to the shape of the last.

20. In a machine of the class described, a jack supporting a last, a former, means to clamp and mold a sole-blank between the former and the shoe on the last, a carriage, a slide carried thereby and mounted to move at right angles to the direction of movement of said carriage, said slide carrying a support for the under side of the sole, a pivotally-mounted guide-wheel adapted to rest on top of the sole and contact with the shoe on the last, means to propel the carriage around the shoe, and means to preserve the contact of the guide-wheel with the shoe, whereby the sole is rounded to the shape of the last.

21. In a machine of the class described, a jack forming a support for the last, a former, means to clamp and mold a sole-blank between the former and the shoe on the last, a carriage, said carriage having mounted thereon a support for the under side of the sole, a knife, and a guide adapted to rest on the top of the sole, and bear against the shoe on the last, means to propel the carriage around the shoe, and means to maintain the contact of the guide with the shoe, whereby the sole is rounded to the shape of the last.

22. In a machine of the class described, a jack supporting a last, a former, means to clamp a sole-blank between the former and last, sole-rounding mechanism, said mechanism being guided by the last, and sole-channelling mechanism.

23. In a machine of the class described, a jack supporting a last, a former, means to clamp a sole-blank between the former and last, sole-rounding mechanism, said mechanism being guided by the last, and sole-channelling mechanism.

24. In a machine of the class described, a jack supporting a last, a former, means to clamp a sole-blank between the former and the shoe on the last, a carriage supporting sole rounding and channelling knives, means

to propel the carriage around the sole, and means controlled by the last to guide said knives.

25. In a machine of the class described, a jack supporting a last, a former, means to clamp a sole-blank between the former and the shoe on the last, a carriage supporting sole rounding and channelling knives, means to propel the carriage around the sole, and means controlled by the last to guide said knives, each of said knives having a turning movement, whereby they may be adapted to the curvature of the sole.

26. In a machine of the class described, a jack supporting a last, a former, means to clamp the sole between the former and the shoe on the last, a carriage supporting a sole-rounding knife, and a channelling-knife, said channelling-knife being adjustable, means to propel the carriage around the sole, and means controlled by the last to guide the said knives.

27. In a machine of the class described, a jack supporting the last, a former, means to clamp a sole-blank between the former and the shoe on the last, a carriage, a guide therefor extending around the sole, a slide on the carriage, sole rounding and channelling knives mounted on the slide, and means to propel the carriage around the shoe, and means controlled by the last to guide the knives.

28. In a machine of the class described, a jack supporting the last, a former, means to clamp a sole-blank between the former and the shoe on the last, a carriage, a guide therefor extending around the sole, a slide on the carriage, sole rounding and channelling knives mounted on the slide, and means to propel the carriage around the shoe, and means controlled by the last to guide the knives.

29. In a machine of the class described, a jack supporting the last, a former, means to clamp a sole-blank between the former and the shoe on the last, a carriage, a slide carried thereby, a sole-rounding knife and a channelling-knife mounted on the slide, a guide also mounted on the slide and adapted to contact with the shoe on the last, means to propel the carriage around the shoe, and means to maintain the constant contact of the guide with the shoe on the last.

30. In a machine of the class described, a jack supporting a last, a former, means to clamp a sole-blank between the former and the shoe on the last and the former, the said former being detachably mounted on the support, whereby either right or left formers may be used, a cutting mechanism contained by said support, said cutting mechanism including a knife, means to move the cutting mechanism around the sole, and means controlled by the last to guide the knife whereby the sole is rounded to the shape of the last.

31. In a machine of the class described, a jack to support a last, a support, a former detachably carried thereby, whereby either right or left formers may be used, means to clamp a sole-blank between the shoe on the last and the former, a carriage mounted on the support and guided thereby, a slide on the carriage movable at right angles to the direction of movement of the carriage, said slide carrying a knife and a guiding means adapted to contact with the shoe on the last, means to move the carriage around the shoe, and means to preserve the contact of the guiding means with the shoe whereby the sole is rounded to the shape of the last.

32. In a machine of the class described, a jack supporting a last, a support, a former detachably carried thereby, whereby either right or left formers may be used, means to clamp a sole-blank between the shoe on the last and the former, sole-rounding mechanism mounted on said support and including a knife, means to move said knife around the sole, sole-channelling mechanism operated in unison with the sole-rounding mechanism, and means controlled by the last to guide both the sole-rounding and sole-channelling mechanisms, whereby the sole is rounded to the shape of the last.

33. In a machine of the class described, a jack supporting the last, a support, a former detachably carried thereby, whereby either right or left formers may be used, means to clamp a sole-blank between the shoe on the last and the former, a carriage mounted on the support and guided thereby, a sole-rounding knife and an adjustable channelling-knife each knife yieldably mounted on said carriage, a guide on the carriage and adapted to contact with the shoe on the last, means to move the carriage around the shoe, and means to preserve the contact of the guide with the shoe, whereby the sole is rounded to the shape of the last.

34. In a machine of the class described, a jack to support a luted shoe, a former, a carriage, a guideway therefor extending around the shoe, and means controlled by the last to guide the carriage, whereby the sole is rounded to the shape of the last.

a knife yieldably mounted on said carriage, means to move the carriage around the shoe, and means controlled by the last to guide the knife.

25. In a machine of the class described, a non-rotatable jack to support a luted shoe, rounding mechanism including a carriage, a rounding-knife yieldably supported thereon, means to propel the carriage around the shoe, and means controlled by the last to guide the knife, whereby the sole is rounded to the shape of the last.

26. In a machine of the class described, a non-rotatable jack to support a luted shoe, channeling mechanism including a carriage, a channeling-knife yieldably supported thereon, means to propel the carriage around the shoe, and means controlled by the last to guide the knife.

27. In a machine of the class described, a non-rotatable jack to support a luted shoe, rounding and channeling mechanisms including a rounding-knife and a channeling-knife, and means controlled by the last to guide each of said knives.

28. In a machine of the class described, a non-rotatable jack to support a luted shoe, rounding and channeling mechanisms including a carriage, a rounding-knife and a channeling-knife yieldably supported thereon, means to propel the carriage around the shoe, and means controlled by the last to guide the said knives.

698,258. GRAIN-CLEANING SCREEN. CHASLES CLARK, Webster City, Iowa. Filed May 11, 1901. Serial No. 98,819. (No model.)

Claim.—1. In a grain-separating screen and in combination with a frame, and a screening-surface of slats pivotally mounted, each slat having transverse ridges and channels terminating in a scalloped overhanging edge, each channel having a depression 10 in the underhanging part of the slat and a flat transverse surface 20 interrupting said channel and joining the upper edge of said depression, for the purpose stated.

2. In a grain-separating screen and in combination with a frame, a screening-surface composed of a plurality of pivotally-mounted adjustable slats in parallel transverse lapping relation in separate sections, each slat having ridges and between them channels in the line of the flow over the screen and terminating in a scalloped overhanging edge, the channels having a width greater than that of the ridges and terminating in depressions or cavities in its underhanging part and transverse ridges forming a flat surface in each channel between the scalloped edge and the cavities for the purpose stated.

3. In a grain-separating screen and in combination with a frame, a screening-surface composed of a plurality of pivotally-mounted adjustable slats in parallel transverse lapping relation in separate sections, each slat overhanging the next adjacent slat and formed with transverse ridges and between them channels which terminate in half-circles at the overhanging edge and in alignment with the flow over the screen, the channels forming chutes beneath the half-circles at the edge of each slat, whereby the grain is free to have a movement toward and over the forward and toward and over the forward edges of each slat for the purpose stated.

4. In a grain-separating screen and in combination with a frame, a screening-surface composed of a plurality of pivotally-mounted adjustable slats in parallel transverse relation in separate sections, each slat over-

hanging the next adjacent slat and formed with ridges and channels in the line of the flow over the screen, terminating in a scalloped edge, a fixed plate for each screen-section along its receiving and having a fingered edge corresponding to the ridges and channels of the slats and having a ridge or raised corrugation back of and parallel with its fingered edge, for the purpose stated.

5. In a grain-separating screen and in combination with a frame, and a screening-surface, the fingered plate, placed at the receiving end frame-bar having a convex corrugation immediately of and rising from its width, said bar being constructed at both sides of said corrugation for the purpose stated.

6. In a grain-separating screen and in combination with a frame, a plurality of pivotally-mounted adjustable slats in parallel transverse relation in separate sections, each slat overhanging the next adjacent slat and formed with transverse ridges and channels terminating in a scalloped or fingered edge and in alignment from the receiving to the delivering end of the screen, a fixed plate for each screen-section along its receiving end having a fingered edge corresponding to the ridges and channels of the slats and a ridge or raised corrugation back of and parallel with its fingered edge, and the slat at the delivering end of the screen overhanging the frame-bar and terminating in an unbroken or straight edge.

7. In a grain-separating screen and in combination with a frame, a plurality of pivotally-mounted adjustable slats in parallel relation in separate sections, each slat overhanging the next adjacent slat, means rigidly connecting the pivot-mounting of each slat, a bar freely suspended by said means, curved and horizontally connecting one end of the suspended bar with the frame, a nut on said screw-rod for adjusting the suspended bar for adjusting the relative relation of the overhanging parts of the slats to each other and means connecting the suspended bar and the frame whereby the adjustment of said bar is automatically caused to indicate by said means the relation of the slats to each other and thereby the size of the openings between their overhanging edges.

8. In a grain-separating screen and in combination with a frame, a plurality of pivotally-mounted adjustable slats in parallel relation in separate sections, each slat overhanging the next adjacent slat, means rigidly connecting the pivot-mounting of each slat, a bar freely suspended by said means, means for adjusting said bar to adjust the relative relation of the overhanging parts of the slats to each other, a rock-rod mounted on the frame having a tapered end engaging the end of the suspended bar, a scale-plate external of the frame and a pointer-arm on the rock-rod arranged to indicate by the rocking of the rod and said scale, the relation which the adjustment of the suspended bar will automatically cause to be given to the slats whereby to show the size of the openings between the overhanging edges of the slats.

9. In a grain-separating screen and in combination with a frame, a screening-surface composed of a plurality of pivotally-mounted adjustable slats, formed with transverse ridges and channels terminating in a scalloped edge, the slat at the delivering end of the screen overhanging the frame-bar and terminating in an unbroken or straight edge, a fixed plate on the frame at the receiving end of the screen having a fingered edge corresponding to the scalloped edge of the slats.

10. A screening-surface composed of a plurality of pivotally-mounted adjustable slats formed with transverse ridges and channels terminating in a scalloped edge, the slat at the delivering end of the screen overhanging the frame-bar and terminating in an unbroken or straight edge, a plate fixed on the bar at the receiving end of the screen having a fingered edge corresponding to the scalloped edge overhanging said frame-bar and having a ridge or raised corrugation back of a parallel with its fingered edge.

11. In a grain-separating screen and in combination with the screen-frame and metal slats arranged therein in separate sections, a pivot-forming rod for each slat, each of said slats having its edge doubled under in a lap having its edge bent over the said rod and soldered thereto, and means for adjusting said slats.

698,259. CONVERTIBLE CAR. HENRY W. COVINE, Webster City, N. Y. Filed Jan. 7, 1902. Serial No. 98,722. (No model.)

Claim.—1. In a convertible car, the combination with the car-body, having members adjacent a side opening each provided with a sideways-groove and at the upper end with a laterally-extended pocket having an outwardly and downwardly inclined bottom communicating with said groove; of a plurality of panels movable along said groove and adapted to rest therein one upon another, said panels having contiguous edge portions inclined downwardly toward the side adjacent said pocket whereby the upper panel can be lifted by means of a lower panel and deflected into said pocket, substantially as described.

2. In a convertible car, the combination with the car-body, having members adjacent a side opening each provided with a sideways-groove and at the upper end with a laterally-extended pocket communicating with said groove; of a panel movable along said groove and capable of deflection into said pocket and adapted to rest therein, substantially as described.

and a yielding keeper for retaining the panel in the pocket, substantially as described.

3. In a convertible car, the combination with the car-body having members adjacent a side opening each provided with a sideways-groove and at the upper end with a laterally-extended pocket having an outwardly and downwardly inclined bottom and adapted to receive a plurality of panels, side by side; of a plurality of panels movable along grooves in said members and adapted to be supported side by side in said pocket, substantially as described.

4. In a convertible car, the combination with a car-body having members adjacent a side opening each provided with a sideways-groove and at the upper end with a laterally-extended pocket communicating with said groove and adapted to receive a plurality of panels side by side; of a plurality of panels movable along said groove and adapted to rest therein one upon another, said panels having contiguous edge portions inclined downwardly toward the side adjacent said pocket whereby the upper panel can be lifted by means of a lower panel and deflected into said pocket, substantially as described.

5. In a convertible car, the combination with the car-body having members adjacent a side opening each provided with a sideways-groove and at the upper end with a laterally-extended pocket having an outwardly and downwardly inclined bottom communicating with said groove and adapted to receive a plurality of panels side by side; of a plurality of panels movable along said groove and adapted to rest therein one upon another, said panels having contiguous edge portions inclined similarly to the inclined bottom of said pocket, and a yielding keeper for retaining the panels side by side in the pocket, substantially as described.

6. In a convertible car, the combination with the car-body having members adjacent a side opening each provided with a sideways-groove and at the upper end with a laterally-extended pocket communicating with said groove and adapted to receive a plurality of panels side by side; of a plurality of panels movable along said groove and adapted to rest therein one upon another, said panels having contiguous edge portions inclined similarly to the inclined bottom of said pocket, and a yielding keeper for retaining the panels side by side in the pocket, substantially as described.

7. In a convertible car, the combination with the car-body having members adjacent a side opening each provided with a sideways-groove, and at the upper end with a laterally-extended pocket having an outwardly and downwardly inclined bottom communicating with said groove and adapted to receive a plurality of panels side by side; of a plurality of panels movable along said groove and adapted to rest therein one upon another, said panels having contiguous edge portions inclined similarly to the inclined bottom of said pocket, and a yielding keeper for retaining the panels side by side in the pocket, substantially as described.

698,260. ART OF TRANSMITTING INTELLIGENCE. ALBERT C. GARDNER, Hanover, N. H., and GEORGE C. BERRY, Port Haven, Va., assignors to the Grebe-Spicer Intelligence Transmission Company, Cleveland, Ohio, a Corporation of Ohio. Filed Nov. 9, 1901. Serial No. 911,578. (No model.)

Claim.—1. The herein-described improvement in automatic telegraphy consisting in improving the characters of a code upon an alternating electric current, gradually rising and falling in strength, by adjusting the makes and breaks of circuit to the difference in phase between the impressed electromotive-force wave and the resultant current-wave so as to open the circuit at times when the current is naturally zero and to close the circuit at times when the current would have been zero had it been allowed to flow uninterruptedly and then to transmit or suppress determinate units of the current in definite order or succession in accordance with each code, and making at the receiving end of the line a visual record showing each pulse transmitted or suppressed, as and for the purpose described.

2. In a transmitting apparatus for code telegraphy, the combination substantially as described, of means for generating an electromotive force gradually rising and falling in value, as described, a transmitter opening synchronously therewith and having a proposed tape or sheet and transmitting-dials adjusted, as described, with reference to the difference in phase between the impressed electromotive-force wave and the resultant current-wave so as to cause the circuit to be opened and closed when the current is naturally zero, as described, and a receiving instrument adapted to make a visual record of the individual pulses transmitted and suppressed.

3. In a transmitter for telegraphy, the combination with an alternating-current generator producing an electromotive force gradually rising and falling in value, as described, and the electric circuit traversed by alternating electric current flowing from said generator, of circuit-controlling device operated synchronously with said generator and comprising a tape or sheet in the working circuit over which said alternating current flows and spaced or adjusted as described with reference to the difference in phase between the impressed electromotive-force wave and the resultant current-wave so as to open the circuit at or about the time the current flowing over said circuit is naturally zero and to close the circuit at times when the current would have been zero had it been allowed to flow without interruption.

4. The combination, substantially as described, in a transmitter for code telegraphy, of a dynamo-generator and a transmitting instrument operated synchronously with said generator and having a transmitting-dial and perforated tape or sheet organized and spaced or adjusted as described with reference to the difference in phase between the impressed electromotive-force wave and the resultant current-wave so as to stop the flow of the alternating current over the circuit at instants when the current is zero and to cause the flow to be resumed at instants when the current would be naturally zero had its flow not been interrupted, and a

resolving instrument adapted to record individual cycles of the current, as and for the purpose described.

5. In a system of telegraphy, the combination with means for generating a varying electromotive force of sine-wave form, of a prepared tape adapted to suppress and transmit definite or predetermined pulses of the varying current produced by said electromotive force by makes and breaks of circuit adjusted with reference to the difference in phase between the varying electromotive-force wave and the resultant current-wave as to interrupt and reestablish circuit when the current is naturally zero, as described, and a receiving apparatus adapted to make a record of the individual pulses so as to show the order and relation of the transmitted and suppressed pulses.

6. The combination with an electric generator developing an alternating electromotive force gradually rising and falling in value, of a transmitting-cylinder and a perforated tape movable at a speed synchronous with that of the generator for controlling the flow of currents developed by said electromotive force over a circuit, said perforations being so arranged and the cylinder so adjusted with reference to the difference in phase between the alternating electromotive-force wave and resultant current-wave that complete cycles will be transmitted or suppressed by makes and breaks of circuit at instants when the current is naturally zero as set forth, and a receiver adapted to respond to each pulsation, as and for the purpose described.

7. The combination with a continuously-operating alternating generator of electromotive force gradually rising and falling in value, of means for controlling the circuit adjusted as described with reference to the difference in phase between the alternating electromotive-force wave and the resultant current-wave so as to transmit individual cycles of the current either positive or negative, beginning and ending at instants when the current is naturally zero as described, and in any order or succession, and a recording apparatus responsive to the individual cycles whether of the same or of the opposite polarity successively.

8. The combination with an alternating electromotive-force generator developing an electromotive force gradually rising and falling in value and the electric circuit connected thereto, of a circuit-breaking tape or sheet and transmitting-cylinder in said circuit spaced and adjusted, as described, with reference to the difference in phase between the alternating electromotive-force wave and the resultant current-wave so as to open the circuit when the current is naturally zero, and to close the circuit when the current would have been zero had it been allowed to flow without interruption.

9. The combination with an alternating electromotive-force generator developing an electromotive force gradually rising and falling in value, of circuit making and breaking appliances operating synchronously therewith and comprising a perforated tape or sheet and electrical contacts adapted to meet through the perforations, said appliances being so arranged and adjusted with reference to the difference in phase between the alternating electromotive-force wave and its resultant current-wave that complete determinate cycles beginning and ending at the time of zero current, as described, will be caused to flow over the circuit.

10. The combination in a telegraph of a dynamo-generator of alternating electromotive force of sine-wave or approximately sine-wave form, transmitting apparatus organized and adjusted with reference to the difference in phase between the alternating electromotive-force wave and the resultant current-wave so as to cause determinate cycles of current in any desired order or relation to flow over the circuit beginning and ending when the current is naturally zero, as described, and a receiving apparatus adapted to record the cycles of current individually.

11. The combination with means for producing an alternating electromotive force and means for suppressing a definite cycle or cycles thereof, organized or adjusted with reference to the difference in phase between the impressed electromotive-force wave and the resultant current-wave so as to cause a cycle or cycles of current to flow beginning and ending when the current is naturally zero, of a recorder of the alternations comprising means for producing a beam of polarized light and for rotating said beam by the action of the alternating current, and means for photographing the successive spots of light corresponding to the successive cycles of said current.

698,261. SUMMARIO-CABLE TELEGRAPHY. ALBERT C. OSBORN, Inventor, I. H. and GEORGE O. SPURR, U. S. Army, assignors to the Osborn-Spurrr Intelligence Transmission Company, Cleveland, Ohio, a Corporation of Ohio. Filed Oct. 25, 1902. Removed Oct. 4, 1903. Serial No. 77,708. (No model.)

Claim.—The heretofore-described improvement in cable telegraphy which consists in transmitting the signaling waves or pulses by impressing upon the cable distinct pulses of electromotive force varying in number or order of succession and changing gradually and continuously from zero through a maximum to zero and adjusting the instants of make and break in the transmitter to the difference in phase between the impressed electromotive-force wave and the resultant waves or pulses of current.

1. The heretofore-described improvement in cable telegraphy which consists in transmitting the signaling waves or pulses by impressing upon the cable distinct pulses of electromotive force varying in number or order of succession and changing gradually and continuously from zero through a maximum to zero and adjusting the instants of make and break in the transmitter to the difference in phase between the impressed electromotive-force wave and the resultant waves or pulses of current.

698,262. BRAKE. WALTER A. CROWDER, Chicago, Ill. Filed July 15, 1901. Serial No. 64,704. (No model.)

Claim.—1. The combination with a revolvable shaft, of a drum secured thereto, a brake-band applied thereto, a dotted link to which the ends of said brake-bands are attached, a lever, a pin through which engages the dot in said link and stops which limit the movement of said link circumferentially of said brake-drum, substantially as described.

2. The combination with a revolvable shaft, of a drum secured thereto, a brake-band applied to said drum, a dotted link to which the ends of said brake-band are attached, the dot in said link comprising symmetrical inclined sections, a lever, a pin secured therein which engages the dot in said link, a pin or saddle on which said link runs when in normal adjustment and stops adapted to limit the movement of said link circumferentially of said brake-drum, substantially as described.

3. The combination with a revolvable shaft, of a drum secured thereto, a brake-band applied to said drum, a dotted link to which the ends of said brake-band are attached, the dot in said link comprising inclined sections, a lever and a pin through which engages the dot in said link, substantially as described.

4. The combination with a revolvable shaft, of a drum secured thereto, a brake-band applied to said drum, a dotted link to which the ends of said brake-band are attached, a lever, a pin through which engages the dot in said link and a fixed plate which extends over the brake-drum beneath said link, substantially as described.

5. The combination with a revolvable shaft, of a drum secured thereto, a brake-band applied to said drum, a dotted link to which the ends of said brake-band are attached, a lever, a pin through which engages the dot in said link, a fixed plate which extends over the brake-drum beneath said link, flanges on said plate which extend upwardly on opposite sides of said link and shoulder on said flanges which extend forwardly beyond the sides of said link, substantially as described.

698,268. HAT-TRUNK. ANDREW J. CURRY, St. Louis, Mo., assignor of one-half to Nicholas J. McVey, St. Louis, Mo. Filed Jan. 20, 1902. Serial No. 61,697. (No model.)

Claim.—1. In a hat-trunk, a hat-support mounted to swing upwardly, and a stop in position to engage the hat-brim and keep them from sliding when the hat-support is swung upwardly, substantially as specified.

2. In a hat-trunk, a suitable trunk or box; posts rigidly secured in the trunk or box, the upper ends of said posts being on a level, and serving as supports for a tray; hat-supports hinged to said posts and adapted to swing upwardly; stops in position to engage the hat-brim, and keep them from sliding when the hat-supports are swung upwardly; and means of securing said hat-supports and holding them in their upright position, substantially as specified.

3. In a hat-trunk, the brackets 14 rigidly mounted; the hat-support 15 hinged to the bracket by a pin 16 inserted through the ears 17 of the bracket, and through the head 18 of the hat-support; the flange 19 connecting the upward edges of the ears 17 and serving as a stop; the arm 20 extending backwardly from the head 18 to engage the stop and allow the hat-support to swing upwardly and limit its downward motion to a horizontal position, said hat-support 15 being a wire loop adapted to encircle the crown of the hat, and support the brim; and the leg 22 extending upwardly from the head 18 and the spring 23 extending forwardly and upwardly from the flange 19 to engage the leg 22 and hold the hat-support in its upright position, substantially as specified.

698,264. HERNIAL TRUSS. GEORGE W. DUNN, Philadelphia, Pa. Filed Apr. 15, 1901. Serial No. 64,102. (No model.)

Claim.—In a truss, the combination of a spring-band having a pivot or arbor thereon, with a lever having an arm oblique to said arbor, said lever being pivoted on said arbor, a forwardly-extending pad fixed on said oblique arm, a link pivotally connected to said lever, and a spring having one end fixed to said band and the other end pivotally connected to said link, substantially as specified.

698,265. DEVICE FOR SUPPLYING LIQUIDS. CHARLES E. L. DUNHAM, Paris, France. Filed Feb. 25, 1902. Serial No. 66,989. (No model.)

Claim.—An automatic supply-regulator for liquids at a variable level, characterized by a siphon fixed at the lower extremity of a curve, the upper extremity of which is attached to a cable passing over a pulley to the other end of which is fixed a counterweight partially balancing the weight of the siphon; the curve supporting the siphon being displaced by means

of a rot and hand-wheel, a graduated scale over which passes an index fixed to the curve, indicating for each position of the siphon the volume of the corresponding supply, as above specified.

698,266. FOLDING BOX. DAVID BELLAMY, Toronto, Canada. Filed May 14, 1901. Serial No. 60,200. (No model.)

Claim.—1. A folding box shaped as the frustum of a pyramid and comprising a rectangular bottom; trapezoidal sides hinged to the base; lid-flaps hinged to the upper edges of the sides so that they may be overlapped to form the top of the box; and handle-flaps secured to two opposite lid-flaps, the other two lid-flaps having slots formed therein through which the said handle-flaps may be passed, substantially as described.

2. A blank to form a box shaped as the frustum of a pyramid which consists of a sheet of stiff material cut and creased to form a central rectangle A; trapezoids B at each side of the central rectangle; slitted flaps C at each side of two opposite trapezoids B; and flaps D at the outer ends of the remaining two trapezoids arranged to be projected through the slots in the first-mentioned flaps, substantially as described.

3. A blank to form a box shaped as the frustum of a pyramid which consists of a sheet of stiff material cut and creased to form a central rectangle A, similar regular trapezoids B at each side of the central rectangle; slitted flaps C at each side of two opposite trapezoids, the inner end of each flap forming the same angle with the side of the trapezoid as the said side does with the side of the central rectangle and the outer end being substantially parallel to the inner end; flaps D at the outer ends of the trapezoids not greater in size than spaces formed with the ends of the trapezoids as base and arranged to be projected through the slots in said flaps C, substantially as described.

4. A folding box shaped as the frustum of a pyramid and comprising a rectangular bottom; trapezoidal sides hinged to the base; side flaps hinged to the sides of two opposite trapezoidal sides the inner end of the side flaps being adapted to rest on the bottom of the box; lid-flaps hinged to the upper edges of the sides so that they may be overlapped to form the top of the box; and handle-flaps secured to two opposite lid-flaps, the other two lid-flaps having slots formed therein through which the said handle-flaps may be passed, substantially as described.

5. A folding box shaped as the frustum of a pyramid and comprising a rectangular bottom; trapezoidal sides hinged to the base; lid-flaps hinged to the upper edges of the sides so that they may be overlapped to form the top of the box; handle-flaps secured to one or more of the said lid-flaps, the remaining lid-flaps having slots formed therein through which the said handle-flaps may be passed; and pieces of tough flexible material pasted to the handle-flaps and a portion of the lid-flaps, substantially as described.

698,267. UMBRELLA-BOX AND STRETCHER-JOINT. SAMUEL J. EVANS, Remond, Va. Filed Jan. 24, 1902. Serial No. 91,004. (No model.)

Claim.—In combination, the ribs, a notch having a series of notches through which the ribs pass and spring parts to retain the ribs in the notch, said parts consisting of flat springs having their terminal edges extending across the said notches from one side to the other and in the plane through which the ribs must pass when being removed, substantially as described.

698,268. PROCESS OF MAKING CEMENT. OTTO FRIED, Wurzburg, Germany, assignor to C. A. Kappeler and Wilhelm Schilling, Munich, Germany. Filed Nov. 14, 1900. Serial No. 737,973. (No specimens.)

Claim.—The process of manufacturing white cement, consisting in the admixture of lime and clay as free as possible from iron, together with feldspar, in about the proportions stated, and burning the resultant mass to the verge of fusing, that is to say, beyond the sintering limit.

698,269. RAILWAY SIGNAL APPARATUS. LAURENT GARNIER, Paris, France. Filed Nov. 3, 1900. Serial No. 24,374. (No model.)

Claim.—1. The combination, with a railway-locomotive, of two alarm devices, a source of electricity, two circuit-breakers mounted respectively in corresponding positions on opposite sides of the locomotive, each circuit-breaker comprising a plurality of fixed and swinging blades, contact-pieces adapted to be engaged by certain of said swinging blades, contact-pieces connecting one of said swinging blades of each circuit-breaker with one of said alarm devices and the source of electricity, and contact-pieces connecting the other of said swinging blades in circuit with the other alarm device, substantially as set forth.

2. The combination, with a railway-locomotive, of a circuit-breaker consisting of a plurality of fixed and swinging blades and connected tripping devices located one at each end of the block and comprising each a horizontal shaft and two sets of tripping-arms mounted rotatably on each shaft, each set comprising two arms arranged at right angles, operating-rods, one for each tripping device, connected each with one of said sets of arms, a chain connecting said operating-rods, and cross-arms projecting each from an arm of one of said sets into the path of an arm of the adjacent set, substantially as set forth.

3. In a railway signal apparatus, a forked circuit-breaker adapted to be carried on the locomotive and provided with outer fixed blades and an intermediate fixed stop-blade, a series of hinged blades, one of which is adapted to swing in one direction and the others in the opposite direction, certain of said blades being limited in movement by said stop-blade, contact devices on some of said hinged blades, and contact devices on the locomotive adapted to cooperate with said contact devices of the blades, substantially as set forth.

4. In a railway signal apparatus, a forked circuit-breaker adapted to be carried on the locomotive and provided with a fixed depending stop-blade, hinged blades adapted to swing in one direction, a hinged blade adapted to swing in the opposite direction, contact-coillets on two of said first-named swinging blades, and contact-pins on the locomotive adapted to engage said coillets, signal devices on the locomotive, a source of electricity, and conducting-wires connecting said signal devices, source of electricity and said contact coillets and pins, substantially as set forth.

5. In a railway signal apparatus, the combination with a circuit-breaker consisting of a plurality of fixed and hinged depending blades, and contact devices on the locomotive adapted to cooperate with certain of said hinged blades, of a tripping device consisting of a horizontal spindle, two sets of tripping-arms arranged rotatably thereon and composed each of two tripping-arms, the arms of each device being arranged one after the other lengthwise of the shaft, in positions corresponding to the hinged and fixed blades, an operating-rod connected with one of said sets, and a cross-arm extending from an arm of said set into the path of an arm of the adjacent set, substantially as set forth.

6. In a railway signal apparatus, the combination, with a circuit-breaker consisting of a plurality of fixed and hinged depending blades and contact devices on the locomotive adapted to cooperate with certain of said hinged blades, of a tripping device consisting of a horizontal spindle, two sets of tripping-arms arranged rotatably thereon and composed each of two tripping-arms, the arms of each device being arranged one after the other lengthwise of the shaft, in positions corresponding to the hinged and fixed blades, an operating-rod connected with one of said sets, and a cross-arm extending from an arm of said set into the path of an arm of the adjacent set, substantially as set forth.

7. In a railway signal apparatus, the combination of two oppositely-arranged tripping devices, consisting each of two sets of angularly-arranged tripping-arms, operating-rods, one for one set of each device, connected therewith, cross-arms extending from said sets at the inner side, each into the path of the adjacent set, guide-pulleys between said tripping devices, a chain passing over said pulleys and connecting said operating-rods, chains connected one with each rod and extending therefrom in opposite directions to the connecting-chains, pulleys over which said chains are guided, and weights on said chains, substantially as set forth.

8. In a railway signal apparatus, the combination of a forked circuit-breaker adapted to be carried upon the locomotive and comprising a depending fixed stop-blade, a series of hinged blades, one of which is adapted to swing in one direction and the others in the opposite direction, certain of said blades being limited in movement by said stop-blade, contact-coillets on certain of said blades, contact-pins on the locomotive, adapted to engage the contact-coillets of the blades, alarm devices on the locomotive, controlled by said circuit-breaker, and two oppositely-arranged connected tripping devices comprising each a horizontal spindle, two sets of tripping-arms mounted rotatably thereon, and operating-rods, one for one set of each device, connected therewith, the tripping-arms of said devices being arranged at different distances from the rail in the path of said fixed and swinging blades and adapted to cooperate with the same, substantially as set forth.

698,270. HERALD TRUSS. WILLIAM H. GARNER, Philadelphia, Pa., assignor, by mesne assignments, to J. Edward Lee Company, Conshohocken, Pa., a Corporation of Pennsylvania. Filed Aug. 14, 1900. Serial No. 24,918. (No model.)

Claim.—The herein-described spring-truss, comprising an elastic band B, a pad secured to one end thereof, a spring extending from said pad for a certain distance around the outside of said elastic band, a covering-strip holding said spring to the outside of said band, both spring and covering-strip being of less width than the elastic band, so and for the purpose set forth.

698,270.

698,271. IMPACT-ENGINE. FREDERICK CARPENTIER, St. Johnsbury, Vt. Filed Feb. 12, 1901. Serial No. 67,122. (No model.)

Claim.—1. In a pneumatic hammer, a cylinder, an impact-piston therein, a sleeve detachably secured to one end of the cylinder, said sleeve having a recess formed in one side of the ends at right angles to the cylinder and out of line of the same, a chambered valve-block arranged in said recess and communicating directly with the cylinder, and a fluid-actuated piston-valve arranged within said block, substantially as described.

2. In a pneumatic hammer, a cylinder, an impact-piston, a handle portion having a sleeve by which it is detachably secured to the cylinder, said sleeve having a recess formed in one side of the same at right angles to and out of line of the cylinder, a chambered valve-block arranged in said recess having a differentially-arranged valve-chamber formed therein, and a fluid-actuated and differentially-arranged piston-valve arranged in said valve-chamber, substantially as described.

3. In a pneumatic engine, the combination of a cylinder, a piston movable within said cylinder, a valve controlling the inlet and outlet of the motive fluid to and from the cylinder, said cylinder being provided with a longitudinal opening leading from the valve for the initial passage of the motive fluid, substantially as set forth for the purpose set forth.

4. In a pneumatic hammer, the combination of a cylinder, a piston movable within said cylinder, a valve-block located wholly outside of the cylinder, a differentially-arranged piston-valve located within said valve-block, said valve adapted to move in a line at right angles to and out of line of the cylinder, said cylinder having passages of reduced area communicating with passages of the same area within the valve-block, whereby the motive fluid may be conveyed to the ends of the piston-valve to hold the same in the different positions, said valve being moved by the initial pressure of the motive fluid.

5. In a pneumatic hammer, the combination of a cylinder, a piston movable within said cylinder, a valve-block located wholly outside of the cylinder, a valve arranged within said valve-block and adapted to move at right angles to and out of line of the cylinder, said cylinder having a series of passages of reduced area, and said valve-block having similar passages communicating therewith, the passages of the cylinder opening into the opposite ends of the same, substantially as set forth for the purpose set forth.

6. In a pneumatic hammer, a cylinder, an impact-piston, a handle portion having a sleeve by which it is detachably secured to the cylinder, and cushioning means interposed between said cylinder and the handle portion.

698,272. RACK FOR HAND-STAMPS. FRANK W. GLOVER, Chicago, Ill., assignor, to Charles L. Bedford, Chicago, Ill. Filed June 17, 1901. Serial No. 94,002. (No model.)

Claim.—1. A rack for hand-stamps and like articles comprising a rack-frame consisting of vertical and horizontal bars and means for detachably connecting the horizontal with the vertical bars comprising attaching-pieces secured to the rear faces of the vertical bars and projecting beyond the side margins of the same, said pieces having bayhole-slots in their parts which project at the sides of the vertical bars and the horizontal bars being adapted to overlap the outer faces of said attaching-pieces and being provided with headed studs adapted to engage the said bayhole-slots in the attaching-pieces.

2. A rack for hand-stamps and like articles comprising upright and horizontal bars and means for securing the horizontal to the upright bars comprising attaching-pieces secured to the upright bars and projecting beyond the side margins of the same at both sides thereof, said pieces being provided with a plurality of bayhole-slots in their parts which project beyond said upright bars and the horizontal bars provided with headed studs adapted to engage said bayhole-slots.

3. A rack for hand-stamps and like articles comprising a horizontal supporting-bar, provided with bayhole-slots, supports for said bar adapted for attachment to a wall or vertical surface and constructed to hold the bar at a distance from said wall or vertical surface and a clasp consisting of two spring-arms and a transverse base portion, said transverse base portion being provided with headed studs adapted to engage adjacent bayhole-slots in the said bar.

4. A rack for hand-stamps and like articles comprising a horizontal supporting-bar provided with bayhole-slots, supports for said bar adapted for attachment to a wall or vertical surface and constructed to hold said bar at a distance from said wall or vertical surface and a clasp consisting of two spring-arms and a connecting base portion, said base portion being provided with two headed studs adapted to engage two adjacent bayhole-slots in the supporting-bar, said headed studs having elastic or resilient connection with the clasp so as to produce spring-pressed engagement of the heads of the studs with the supporting-bar.

5. A rack for hand-stamps and like articles comprising a horizontal supporting-bar provided with bayhole-slots, supports for said bar adapted for attachment to a wall or vertical surface and supports being adapted to hold the bar at a distance from said wall or vertical surface and a clasp consisting of a piece of spring metal bent to form two spring-arms and a transverse base portion, said base portion being provided with two headed studs and being outwardly bent or curved in its central part.

6. A rack for hand-stamps or like articles comprising a supporting-bar provided with a plurality of bayhole-slots arranged side by side and having counter-sunk recesses in its rear face at the narrower ends of said bayhole-slots, and a clasp consisting of two spring-arms and a connecting or base portion, said base portion having two headed studs having elastic or resilient connection with the clasp.

7. A rack for hand-stamps and like articles comprising a bar having a plurality of bayhole-slots, a clasp provided with headed studs adapted for engagement with the slots of said bar, and a tag provided with holes

for the said shaft, and adapted to be placed and held between the shaft and the bar.

698,273. WIRE-DRAWING. WILLIAM J. GLOVER, St. Helena, England. Filed June 12, 1901. Serial No. 64,398. (No model.)

Claim.—1. In a wire-drawing machine, a drawing-roll constructed in the form of a hollow drum having a closed periphery and means for introducing cooling fluid to the hollow of said drum and discharging it therefrom without its coming in contact with the wire to be drawn, substantially as described.

2. In the drawing-roll of a wire-drawing machine, the combination of a base, a side disk forming part of and projecting from said base, a steel rim let into an annular cavity in the side of said disk, a facing-disk forming with said side disk and rim a peripherally-closed drum, and means for admitting a cooling fluid to the interior of said drum without said fluid coming in contact with the wire to be drawn, substantially as described.

3. In a wire-drawing machine the drawing-roll of which are formed as hollow peripherally-closed drums, an arrangement for conveying a cooling fluid to the interior of said drums which consists of a hollow shaft, means of communication between said shaft and the interior of the hollow drum mounted thereon, and a stationary pipe passing through a gland into the interior of said shaft, whereby a cooling fluid may be introduced into said shaft while it is in rotation, substantially as described.

4. In a wire-drawing machine, the drawing-roll of which are formed as hollow peripherally-closed drums, an arrangement for conveying a cooling fluid to the interior of said drums which consists of a hollow shaft, means of communication between said hollow shaft and the interior of the hollow drum mounted thereon, a stationary supply-pipe inserted in the end of said hollow shaft, a collar within said shaft at the end of said supply-pipe, whereby rotation of the hollow shaft about the supply-pipe is permitted, and leakage of the cooling fluid is prevented, substantially as described.

5. In a wire-drawing machine, the drawing-roll of which are formed as hollow peripherally-closed drums, an arrangement for circulating a cooling fluid in said drums, which consists of a hollow shaft, passages communicating between said hollow shaft and the interior of said hollow drums, and means for permitting the outflow of said fluid from said drums without said fluid coming in contact with the wire to be drawn, substantially as described.

698,274. ELECTRIC FLY-TRAP. HOWEN E. GANNON, Providence, R. I. Filed Aug. 20, 1901. Serial No. 72,604. (No model.)

Claim.—1. An electric insect-killer, comprising a frame of insulating material and having a support for a belt, and positive and negative wires connected with a source of electric energy, and wound around the said frame to form grids on both the front and rear of the frame, the grids including the belt, substantially as shown and described.

2. An electric insect-killer, comprising a frame of insulating material and having a support for a belt, positive and negative wires connected with a source of electric energy, and wound around the said frame to form grids on both the front and rear of the frame, the grids including the belt, and a shelf suspended from the said frame and having positive and negative wires connected with the wires of the frame, as set forth.

3. An electric insect-killer, comprising a frame of insulating material and having a support for a belt, positive and negative wires connected with a source of electric energy, and wound around the said frame to form grids on both the front and rear of the frame, the grids including the belt, a shelf, means for suspending it from the said frame, and positive and negative wires wound around said shelf and connected by the said suspension means with the wires of the said frame, as set forth.

4. An electric insect-killer, comprising a frame of insulating material and consisting of a center plate, top and bottom caps, strips intermediate of the said caps and extending along the front and rear of the center plate to form supports for a belt, and positive and negative wires connected with a source of electric energy, and wound around the said caps and stretched over said strips to form grids on both the front and rear of the frame, the grids including the belt, substantially as shown and described.

698,275. SELF-CLOSING DOOR FOR MINES. FRIEDRICH OTT, Riedelshausen, Germany. Filed June 14, 1901. Serial No. 64,600. (No model.)

Claim.—A gate for mine-shafts consisting of a curved inverted-U-shaped bar, pivot-bolts connecting the same near its upper end to the timbers of the mine-level adjacent to said shaft, guides on the sides of said level, a flat-bar connecting the lower ends of said U-bar, a cross-rod supported upon said timbers above said flat-bar, chains connecting said rod and flat-bar, substantially as described.

698,276. LOCOMOTIVE-ENGINE. CHRISTIAN KAMMER, Berlin, Germany. Filed Dec. 15, 1901. Serial No. 85,006. (No model.)

Claim.—1. A compound locomotive provided at each side near the forward end thereof with a pair of cylinders arranged tandem but laterally of a direct line joining their longitudinal axis.

2. A compound locomotive-engine, provided with a pair of cylinders at each side near the forward end thereof and arranged tandem but laterally of a direct line joining their longitudinal axis, a pair of crank-pins carried by the drive-wheel of the locomotive and set at an angle of one hundred and eighty degrees to each other, suitable connections between the crank-pins and the cylinders, and means for connecting the cylinders to each other for the purpose of taking up strains set up in the cylinders in opposite directions.

698,277. BOYCE-SUPPORT. CHARLES HANCOCK, New York, N. Y. Filed Jan. 3, 1902. Serial No. 87,067. (No model.)

Claim.—1. A support comprising base-pieces pivoted to one another and each made to double or fold, and jaws pivoted or swinging on the base-pieces.

2. A support comprising base-pieces each piece composed of pivoted sections adapted to double or fold to one another, said pivot being made to also pivotally enter the several pieces to enable the latter to be swung relatively to one another, and a clamp or jaws carried by the base-pieces.

3. A support comprising a base and jaws pivoted to the base, said jaws being adapted to clamp a wheel rim or tire and provided with a neck or neck-section adapted to clamp a spoke.

4. A support comprising a base and jaws pivoted to the base, said jaws being adapted to clamp a wheel rim or tire and provided with a neck or neck-section adapted to clamp a spoke, and means for locking the jaws and neck about a rim and spoke.

5. A support comprising a base and jaws pivoted to the base, said jaws being adapted to clamp a wheel rim or tire and provided with a neck or neck-section adapted to clamp a spoke, and a lock for the jaws consisting of a split and threaded ring adapted to be passed about a spoke and secured to the closed neck-section.

698,278. LAMP-HANGER. HENRY J. HARRISON, Jamaica, Alaska. Filed May 13, 1901. Serial No. 63,599. (No model.)

Claim.—A lamp-hanger, comprising a frame having two depending parts, a shaft mounted to turn in said parts, the shaft extending between them, a spring actuating the shaft, a drum mounted to turn in the depending parts of the frame below the shaft, gearing connecting the drum with the shaft, two smaller concentric drums integral to one end of the drum concentric with the axis thereof, contact-fingers fastened to the adjacent depending part of the frame and bearing respectively on said smaller concentric drums, electrical conductors leading to the contact-fingers, electrical conductors wound on the drum and having connection respectively with the contact-fingers, and means working with the drum to control its movement.

698,279. FILM-STRIP MOUNTING FOR LOOM. LEONARD E. HARTLEY, THOMAS E. HARRIS, and JOHN EDWARDS, Lowell, Mass. Filed Dec. 11, 1901. Serial No. 85,007. (No model.)

Claim.—1. In a film-strip motion picture camera, the combination of the film-strip, the film-strip intermediate mechanism connecting said slide and slide and a yielding device arranged between said slide and said slide and adapted to permit the retracting of said slide without stopping said film.

2. In a film-strip motion picture camera, the combination of the film-strip, provided with a crank, a film-strip lever, a link connecting said crank and said lever, the lever-slide immediately operated by said lever, and a yielding device, arranged between said crank and said slide to permit the forward movement of said slide to be arrested before said crank has attained its greatest forward throw.

3. In a film-strip motion picture camera, the combination of the film-strip, provided with a crank, a film-strip lever, a link, pivoted at

one end to said crank and at the other end provided with a longitudinal slot, a block, arranged to slide in said slot, and to turn on a stud with which said lever is provided, a spring, normally to hold said block at the end of said slot furthest from said crank, the lever-slide and connecting means between said lever-slide and said lever.

4. In a film-strip motion picture camera, the combination of the film-strip, provided with a crank, a film-strip lever, a link, pivoted at one end to said crank and at the other end provided with a longitudinal slot, a block, arranged to slide in said slot, a spring, arranged in said slot between said block and the end of said slot nearest said crank, a stud projecting from said lever and adapted to turn in a hole with which said block is provided, the lever-slide and connecting means between said lever-slide and said lever.

698,280. MATRIX-BAND RETAINER. ARTHUR J. REIMER, San Francisco, Cal. Filed Sept. 22, 1901. Serial No. 78,218. (No model.)

Claim.—The matrix-band retainer comprising two bands, the parallel guides passing through perforations in one of said bands and guiding the movement of the bands toward each other, means for so moving said bands to and from each other, and the matrix-band having at each end two perforations through which the guides pass, substantially as described.

698,281. BELLING HEATH. ALFRED HEATH, Boston, France. Filed Sept. 1, 1901. Serial No. 78,217. (No model.)

Claim.—In a roller-skate the combination with a frame, a driving-wheel having a pulley on its hub, a foot-pedal pivoted at its forward end to the frame, a connecting-rod pivoted to the pedal, a gear-wheel journaled in the frame and having a mesh with the pulley of its rim, a crank-pin thereon engaging a hole in the connecting-rod, a lever pivoted to the frame, an intermediate gear-wheel journaled at the two ends of said lever,

a spring normally pressing the lever down and the gear out of engagement, and a part-arm rigid with the pivoted lever having a tooth to engage the notch in the rim of the crank gear-wheel and hold the gear out of engagement, and the first-pedal fixed in a horizontal position, substantially as described.

698,983. FASTENING FOR DOORS OR SHUT LIKE. JAMES H. MOYER, Ashland, Vermont. Filed July 27, 1904. Serial No. 79,922. (No model.)

Claim.—1. In a fastening for doors and shut like the combination of a latch-lever provided with a projection at its free end and adapted to be hinged to the side frame of the door, a catch adapted to hold the lever in a vertical position and to permit its release, a stop-plate secured to a plate adapted to be attached to the door or shut like, a bolt adapted to slide in guides mounted on said plate and adapted to being moved into its closed position to form in combination with the end of said stop-plate an eye including said latch-lever and a catch for holding the bolt in locked position, substantially as set forth.

2. In a fastening for doors and shut like the combination of a latch-lever provided with projection at its free end and adapted to be hinged to the door-frame, a catch adapted to hold said lever in a vertical position and to permit its release, a stop-plate secured to a plate adapted to be attached to the door, a bolt adapted to slide in guides mounted on said plate and to form in combination with the end of said stop-plate an eye including said latch-lever, and a spring normally pressing said bolt into its locked position, substantially as set forth.

3. In a fastening for doors and shut like the combination of a latch-lever, provided with projection at its free end and adapted to be hinged to the door-frame, a catch adapted to hold said lever in a vertical position and to permit its release, a stop-plate secured to a plate adapted to be attached to the door, a bolt adapted to slide in guides mounted on said plate and to form in combination with the end of said stop-plate an eye including said latch-lever, a spring normally pressing said bolt into its locked position, and a catch adapted to keep said bolt in either its locking or open position, substantially as set forth.

4. A fastening device, comprising a swinging latch-lever, a spring-pressed bolt having a lateral projection at its free end, a stop-plate adapted to form with the bolt an eye to receive the latch-lever, and a locking device for said bolt, substantially as specified.

698,988. REVERSING-VALVE FOR REGENERATIVE GAS-FURNACES. HARRY EVATT and JOHN McNEIL, Cleveland, Ohio, assignors to the Wellman-Burner Engineering Company, Cleveland, Ohio, a Corporation of Ohio. Filed Dec. 19, 1904. Serial No. 68,576. (No model.)

Claim.—1. A reversing-valve for regenerative gas-furnaces consisting of a box-like casing, a lining of refractory material for said casing, a transverse partition dividing the casing into two chambers, and blocks extending from one side of the casing to the partition, said partition together with the blocks and refractory lining being supported on plates extend-

ing along the edges and across the bottom of the casing, substantially as described.

2. A box-like casing having its lower side open, a horizontal plate fixed to the lower edge of the casing extending on both sides of the lining of the walls of the casing, and a refractory lining for the casing carried on the inwardly-projecting part of said plate, the outwardly-extending portion of the plate having a downwardly-extending annular flange outside the lining of the walls of the casing, substantially as specified.

3. A reversing-valve for regenerative gas-furnaces consisting of a conical-shaped casing having a partition dividing it into two chambers and open on its lower face, the edges of the openings of the chambers in said face having downwardly-projecting flanges, and a plate extending around the outside of the casing also having a downwardly-projecting flange, said flange extending downwardly to a greater length than the first-mentioned flange, substantially as specified.

4. A reversing-valve for regenerative gas-furnaces consisting of a casing divided by a transverse partition into two chambers, said chambers being open on their lower face, the edges of each opening being surrounded by a downwardly-projecting flange, a plate extending in an approximately horizontal plane and fixed to the lower portion of the casing, said plate also having a downwardly-projecting flange outside of the first flange, said second flange being deeper in form and projecting down to a level below the lower edge of the first flange, substantially as specified.

5. The combination of a box structure for regenerative gas-furnaces provided with four fine openings, a casing-pit surrounding said openings and extending between the same, a reversing-valve having a transverse partition dividing it into two chambers open on their lower face, with downwardly-projecting flanges extending around said openings, and a plate fixed to the valve having a second flange extending around the casing, said flange being constructed to enter the said casing-pit, substantially as specified.

6. The combination of a box structure having four fine openings into it, a casing-pit extending around said fine openings, and casing-pits of relatively less depth extending around each fine-opening, with a reversing-valve provided with two chambers open on their lower face, the openings from said chambers being provided with downwardly-projecting flanges constructed to enter the shallow casing-pits and a plate extending around the valve provided with a downwardly-extending flange of greater length than those surrounding the openings of the chambers, said flange being constructed to enter the outer casing-pit, substantially as specified.

7. A reversing-valve for regenerative gas-furnaces, the same consisting of a casing, a framework for said casing, means on the framework supported to the casing for raising the same and a cylinder also carried on the casing having grooves in its interior and a pin on the means connecting the raising means with the casing, constructed to engage said grooves, whereby the casing is given a partial revolution as it is raised or lowered, together with means for causing the pin to traverse the grooves in but a single direction substantially as specified.

8. A reversing-valve for regenerative gas-furnaces, the same consisting of a casing, a framework for the same, supporting means for raising said casing at will, a rod connecting the casing to the said means, two members consisting of a pin and a body having grooves, one of said members being attached to said rod and the other member being carried by the framework and engaging the first member, said members serving to partially revolve the casing as it is raised or lowered, together with means for causing the pin to move through the grooves in a constant direction, substantially as described.

698,984. WATER-POWER. THOMAS E. HYDE and ALLEN B. BROWN, Youngstown, Ohio. Filed Nov. 20, 1904. Serial No. 64,096. (No model.)

Claim.—1. In a water-tower, a telescopic stand-pipe having a plurality of lockable sections, and one releasing device supported in a fixed location and having locking means common to all of the lockable telescoping sections for effecting a locking thereof when needed, and also providing for the release of the sections one at a time and successively.

2. In a water-tower, a telescopic stand-pipe having lockable telescoping sections, and a single releasing device supported in a fixed location and having locking means common to, and cooperating in a similar manner with, all of said lockable sections.

3. In a water-tower, a telescopic stand-pipe having a stationary base-section and other telescoping lockable sections, and one releasing device carried solely by the base-section and having locking means, common to all of the lockable sections, for effecting the individual locking and releasing thereof.

4. In a water-tower, the telescopic stand-pipe having a base-section and other telescoping lockable sections, and one releasing device mounted upon the upper end of the base-section and having locking means com-

mon to all of the lockable sections for effecting the individual locking and releasing thereof.

5. In a water-tower, a telescopic stand-pipe having lockable telescoping sections each provided with a holding member, and one releasing device comprising a fixed location and having locking means common to, and cooperating in a similar manner with, the holding members of all of said lockable sections.

6. In a water-tower, a telescopic stand-pipe having lockable telescoping sections provided with similar holding members overlying one another when the sections are nested or collapsed, and a single releasing device mounted to operate in a fixed plane and having locking means cooperating in a similar manner with the holding members of the several sections to effect a locking of the sections when needed, and also for the release thereof one at a time and successively.

7. In a water-tower, a telescopic stand-pipe having telescoping sections provided with lug-flanges, and a single releasing device having a corresponding and complementary flange.

8. In a water-tower, a telescopic stand-pipe, having telescoping sections provided at their upper ends with outward flanges having spaced lugs, and a single releasing device having a corresponding and complementary flange.

9. In a water-tower, a telescopic stand-pipe having sections provided at their upper ends with outward flanges having spaced lugs, the outer diameter of the flanges of the different sections being the same, and a single releasing device rotatably supported and having an internal flange overhanging those of the telescoping sections and also provided with a series of spaced lugs.

10. In a water-tower, a telescopic stand-pipe having a base-section and other sections, the latter being provided at their upper ends with outward flanges having spaced lugs, said lugs on the adjacent flanges being alternately rotated, and a single releasing device consisting of a sleeve rotatably supported on the base-section and having an internal flange also provided with a series of spaced lugs.

11. In a water-tower, a telescopic stand-pipe comprising a plurality of telescoping pipe-sections, said sections being provided with cooperating complementary locking and releasing steps, and all excepting the lowermost or base section being provided with an exterior plate-packing including a packing-ring and a detachable binding-ring.

12. In a water-tower, a telescopic stand-pipe comprising a series of telescoping sections, common means for locking all of the telescoping sections, excepting the lowermost one, in their nested position, and also for successively releasing the individual sections one at a time, said lowermost section being a valve-bearing section, and the section next succeeding the same carrying a working platform, and an extension-holder whose base-section is connected with the supporting-frame of the tower and whose top section is connected with said working platform, said extension-holder being extended and collapsed simultaneously with the stand-pipe, substantially as set forth.

698,985. EXPLOSION-ENGINE. MARSH E. RYLAND, Peoria, Ill. Filed May 14, 1904. Serial No. 68,934. (No model.)

Claim.—In an explosion-engine of the four-cycle type, the combination with two tandem cylinders having intermediate abutments, of a pair of cooperating tandem pistons the heads of which work in said cylinders on opposite sides of the cooperating abutments and the stems of which work through said abutments, intake-valves and exhaust-valves opening, respectively, into and from said cylinders, between said abutments and said piston-heads, a crank-shaft having cranks at one end and at right angles in advance of the other and connected one to each of said tandem pistons, and a one-to-two valve-gear for operating said four exhaust-valves in succession involving a series of four rotary tappets driven from said crank-shaft and set slowly degrees apart, whereby an explosion is obtained for each half-revolution of the crank-shaft and for each stroke of the pistons, substantially as described.

698,986. TAP TAP. JAMES A. IRVIN, Philadelphia, Pa. Filed May 12, 1904. Serial No. 68,986. (No model.)

Claim.—1. In a tap tap, the combination with an outer casing, of a balance-wheel arranged to rotate within said casing independently thereof; a spindle fixed in said wheel and extending exterior to said casing; a recess in the interior bottom wall of said casing; and an adjustable bearing-plate fixed in said recess and provided with a stop-bearing for said spindle, substantially as set forth.

2. In a tap tap, the combination with the outer casing, of a balance-wheel arranged to rotate within said casing independently thereof; a spindle fixed in said wheel and extending exterior to said casing; a recess in the interior bottom wall of said casing; a bearing-plate fixed in said recess in engagement with the inner extremity of said spindle; and a screw entered through said casing, within said recess, in adjustable relation with said bearing-plate, substantially as set forth.

3. In a tap tap, the combination with the outer casing A, of the bal-

two-wheel B, arranged to rotate within said casing independently thereof; the spindle D, fixed in said wheel and extending exterior to said casing; the corrugations C, upon the extremity of said spindle exterior to said casing and arranged to cooperate with a driving-rod leaped thereon; the screw A', in the bottom of said casing; the plate E, fitted in said casing and provided with the stop-bearing A, for said spindle D; the bearing-housing G, surrounding said spindle at the top of said casing; and the flange C, upon said housing exterior to said casing, substantially as set forth.

4. In a toy top, the combination with an outer casing; of a balance-wheel arranged to rotate within said casing independently thereof; a spindle fixed in said wheel and extending exterior to said casing, in rotatable relation with the latter; corrugations upon the extremity of said spindle, exterior to said casing, arranged to cooperate with a driving-rod leaped thereon; a bearing-housing surrounding said spindle at the top of said casing; and a metal flange at the top of said casing, arranged to receive the wear of the driving-rod, substantially as set forth.

5. In a toy top, the combination with an outer casing; of a balance-wheel arranged to rotate within said casing independently thereof; a spindle fixed in said wheel and extending exterior to said casing in rotatable relation with the latter; and a series of corrugations upon said spindle exterior to said casing, terminating short of the end of said spindle and arranged to engage a driving-rod leaped upon the latter, substantially as set forth.

6. In a toy top, the combination with an outer casing; of a balance-wheel arranged to rotate within said casing independently thereof; a spindle fixed in said wheel and extending exterior to said casing in rotatable relation with the latter; a series of corrugations upon the free extremity of said spindle exterior to said casing and arranged to engage a driving-rod leaped thereon; and a bearing-plate in the bottom of said casing in engagement with the inner extremity of said spindle, substantially as set forth.

7. In a toy top, the combination with an outer casing; of a balance-wheel arranged to rotate within said casing independently thereof; a spindle fixed in said wheel and extending exterior to said casing, in rotatable relation with the latter; and a series of corrugations upon the free extremity of said spindle exterior to said casing, arranged to engage a driving-rod leaped thereon, substantially as set forth.

8. In a toy top, the combination with the outer casing; of a balance-wheel arranged to rotate within said casing; a spindle fixed in said wheel and extending exterior to said casing; a bearing-housing seated in the upper part of said casing; a bearing-plate in the bottom of said casing in engagement with the inner extremity of said spindle; and a cut-away exterior through said casing in adjustable relation with said bearing-plate, substantially as set forth.

898,987. ROSS-LOCK FOR VEHICLES. ARLEY H. JOHNSON.
Belle Center, Ohio. Filed Dec. 25, 1901. Serial No. 67,610. (No model.)

Claim.—1. In combination with a hub-rod, a plate attached thereto, and having a projecting end provided with an opening, a clamping member moved to an anchoring device and having arms to receive the projecting end of the plate between them, said arms having openings to register with that in the plate, and a locking device to engage said registering openings and secure said plate to said clamp, substantially as described.

2. The combination with a hub-rod of a plate having perforations therein and an aperture at one end thereof, means for attaching said plate to said rod, and a clamp having a loop for engaging a rod, and apertured arms connected with said loop and adapted to engage said plate on opposite sides thereof, and means for locking said plate and arms together.

3. A sub-locking device comprising a plate having longitudinally-located perforations disposed along the opposite sides thereof and provided with an aperture at one end thereof, and a clamping member in the form of a plate fitted upon itself at its center thereby forming a loop for en-

gaging a rod, the end of said plate extending in the same direction in parallel planes and provided with means for attaching them to said perforated plate.

898,988. WRINGING. LAVATHEN W. JOHNSON, JEROME, ARIZ. assignor to David Center and Chas. E. Hothorn, Jerome, Ariz. Filed May 25, 1901. Serial No. 68,981. (No model.)

Claim.—1. The improved wring comprising a shaft having a fixed jaw, and provided with opposite side channels, and two laterally opposite sets, or rows, of teeth on its upper and under sides, the latter being flat intermediate of each set of teeth, and the slidable jaw having side pivots, and interior teeth located at diagonally opposite points, and a curved spring arranged within the slot as shown and described.

2. The improved wring comprising a shaft having a fixed jaw, and provided with opposite side channels, and two laterally opposite sets or rows of teeth on its upper and under sides, the latter being flat intermediate of each set of teeth, and the slidable jaw having side pivots and interior teeth located at diagonally opposite points, and an interior projection located at about the middle of its length, which projection is adapted to bear and slide upon the smooth portion of the shaft intermediate of the upper rows of teeth, and a curved plate-spring arranged as described.

898,989. HIRE-LIFT FOR SHOES. JAMES J. JOHNS, NEW YORK, N. Y. Filed Dec. 4, 1900. Renewed Jan. 10, 1908. Serial No. 69,000. (No model.)

Claim.—1. As a new article of manufacture, a heel-lift for boots and shoes comprising a layer of rubber having a flat tread-surface and the opposite surface provided with a marginal recess and a layer or strip of leather of hesshoe form fitting the said marginal recess and connected thereto at the flat opposing surfaces and edges, substantially as set forth.

2. As a new article of manufacture, a heel-lift for boots and shoes comprising a layer of rubber having a flat tread-surface and the opposite surface provided with a marginal recess, and a layer or strip of leather of hesshoe form fitting the said marginal recess and connected thereto, substantially as set forth.

898,990. FINE WATER HEATER. BENJAMIN F. KENNY, BROOKLYN, N. Y. Filed Jan. 24, 1902. Serial No. 81,126. (No model.)

Claim.—1. In a feed-water heater, a shell, a tube-sheet bolted to said shell, said parts being arranged to form a steam-chamber, the bolts serving to maintain a steam-tight joint, tubes connected with said tube-sheet, a cutting-chamber, a flange depending from the tube-sheet, said flange being bolted to the cutting-chamber, and said bolts serving to maintain a water-tight joint and being independent of the other bolts, and a plurality of chambers between said cutting-chamber and the tube-sheet connected respectively with the tubes and cutting-chamber.

2. In a feed-water heater, a shell having an external annular flange at its base, a tube-sheet bolted to said shell to form a steam-joint, and the bolts serving to maintain a steam-tight joint, tubes inserted by the shell for the circulation of water and steam into said tube-sheet, and the latter having a series of depending walls, and a cutting-chamber bolted to said last-mentioned flange, and the bolts serving to maintain a water-tight joint, and said cutting-chamber having a top arranged to fit against the lower edges of the depending flange and the walls of the tube-sheet.

898,991. GATE. WILLIAM E. KENNY, BROOKLYN, N. Y. Filed Oct. 25, 1900. Serial No. 64,322. (No model.)

Claim.—A gate comprising and uprights having horizontal rails connected thereto, additional uprights connected to all of the rails adjacent to one end of the gate, a pair of levers disposed one at each side of the rails and extending from the upper ends of the last-mentioned uprights downwardly and rearwardly to the lower end of the upright at the rear end of the gate and connected to all of the rails, short uprights connected to the bottom rail of the gate and resting with their upper ends against the under faces of the levers, said levers pivoted to the short uprights and sliding means connected to the levers, said gate being pivoted at the lower end of the rear upright thereof, for movement in a vertical plane.

898,992. TRAPING OF RECOVERING METALS. EDWARD B. KEMMEL, NEW YORK, N. Y. Filed July 2, 1902. Serial No. 82,912. (No specimens.)

Claim.—1. The process of separating and recovering metals from solutions containing them, which consists in flowing over a mass of fragmental carbon which serves as a cathode, a dilute solution of potassium cyanide containing metals in solution, and at the same time subjecting said dilute solution to the action of an electric current having sufficient empyrege and electromotive force of at least five volts, the metals being carbon immersed in a solution of caustic alkali which is separated from the cathode solution by a porous diaphragm.

2. The process of separating and recovering metals from dilute solutions of cyanide containing them which consists in flowing said solutions over and through a fragmental mass of carbon presenting a large surface area, and which carbon mass serves as cathode, a plate or plates of carbon serving as anode, subjecting said flowing solution to the action of an electric current having an electromotive force of five volts or more, and

stopping the flow of dilute solution and flowing over and through the fragmental carbon mass a stronger solution of potassium cyanide and at the same time subjecting the deposited metal to the action of a reversed electric current, not exceeding electromotive force of five volts using the carbon mass as anode and a plate of metal for the cathode.

3. The process of separating and recovering metals from dilute solutions containing them which consists in flowing said solutions over and through a fragmental mass of carbon presenting a large surface area, and which carbon mass serves as a cathode, a plate of carbon immersed in solution of potassium or sodium hydroxide serving as anode, which solution of potassium or sodium hydroxide is separated from the cathode solution by a porous diaphragm, whereby cyanogen set free by an electric current is reconverted to alkali cyanide, subjecting said flowing solution to the action of the electric current having an electromotive force of five volts strength or more until stopping the flow of dilute solution and flowing over and through the fragmental carbon mass a stronger solution of potassium cyanide and then subjecting the deposited metal to the action of a reversed electric current not exceeding an electromotive force of five volts, using the carbon mass as anode and a plate of metal for the cathode.

898,993. ORGANOGRAPHY. CHAS. E. KEMMEL, PORT HAVEN, N. Y. Filed Dec. 12, 1901. Serial No. 69,000. (No model.)

Claim.—1. An organography comprising in its construction an open tank having a cutting-draw with a generally imperforate bottom located within its upper portion, means also within the tank for circulating water and tailings from the lower part of the tank to said trough, and means for moving the tailings which lodge in said trough along the bottom thereof, a tailings-trough from the trough extending through the outer side of the tank, whereby gold or other heavy material will remain at the bottom of the tank while the tailings will be elevated into the trough, and into

stationally and continuously removed therefrom while the water overflows from the trough into the tank, as set forth.

2. An ore-separator comprising in its construction a tank having a vertical flume or cylinder located therein and open at the top and bottom, a circular settling-trough surrounding the upper end of the flume below the upper edge of the tank and adapted to receive water and tailings discharged at the upper end of the flume and to return water to the tank by overflow, means for elevating water through said flume, the said trough being provided with a debris-opening, and means for moving debris around the trough to the opening.

3. An ore-separator comprising in its construction an inverted-cone-shaped tank having a vertical flume or cylinder located therein and open at the top and bottom, a circular settling-trough surrounding the upper end of the flume below the upper edge of the tank and adapted to receive water and tailings discharged at the upper end of the flume and to return water to the tank by overflow, means for elevating water through said flume, the said trough being provided with a debris-opening, and means for moving debris around the trough to said opening, means being provided for removing gold from the bottom of the tank.

4. An ore-separator comprising an inverted-cone-shaped tank having brackets 10 projecting inwardly therefrom, a circular settling-trough resting on said brackets, a vertical cylinder or flume located centrally and having a circular plate or disk connecting its upper end with the trough, means for elevating water within the flume, and scraper-blades movable in said trough, said trough having provision for the discharge of mining debris therefrom and for returning the water to the tank by overflow.

5. An ore-separator comprising an inverted-cone-shaped tank having brackets 10 projecting inwardly therefrom, a circular trough resting on said brackets, a vertical cylinder or flume located centrally and having a circular plate or disk connecting its upper end with the trough, means for elevating water within the flume, scraper-blades movable in said trough, said trough being raised at one portion and having an opening in its bottom, and a chute or spout leading from said opening outside of the tank.

6. An ore-separator comprising an inverted-cone-shaped tank having brackets 10 projecting inwardly therefrom, a circular trough resting on said brackets, a vertical cylinder or flume located centrally and having a circular plate or disk connecting its upper end with the trough, means for elevating water within the flume, a rotatable disk or plate above the flume and means for rotating it, outwardly-projecting arms pivoted to said disk and having scraping-blades pivoted to their outer ends, said trough being raised at one portion and having an opening in its bottom, and a chute or spout leading from said opening outside of the tank.

7. An ore-separator comprising in its construction a tank, a vertical flume or passage mounted centrally in the tank and having a circular trough within the upper portion of the tank and below the upper edge thereof, said trough surrounding and communicating with the upper end of the flume, a shaft having spiral blades mounted in said vertical flume, a disk surrounding said shaft and having arms provided with blades fitting and movable in said trough, said trough being provided with an outlet for tailings, means for rotating the shaft and the scraper-carrying disk, and gearing whereby the shaft rotates at a higher speed than that of the scraper-carrying disk.

698,994. HENRY GO-BOWEN. Broom Elevator, New York, N. Y. Filed Aug. 27, 1901. Serial No. 73,002. (No model.)

Claim.—1. In a merry-go-round, the combination, with a central support having a beveled gear fixed thereon, and a horizontal frame having radial arms and adapted to revolve on said support, of drive-shafts suspended from said arms and having gears meshing with that on the support, a series of short independent crank-shafts geared with said drive-shafts and supported in bearings attached to the frame-bars, a series of seats, and rods extending the same which are loosely connected with said seats, and propelling-rods provided with pulleys and connected with the short crank-shafts and arranged vertically in front of the seats, substantially as shown and described.

2. In a merry-go-round the combination, with the horizontal rotatable frame, a central support for the latter having a master-gear, a series of drive-shafts hung from the frame and having gears meshing with the master-gear, short crank-shafts geared with the drive-shafts, a series of seats, and supporting-rods therefor, which are loosely connected with the

frame and adapted to swing freely outward, and a series of pairs of propelling-rods having pulleys which are vertically adjustable, the said propelling-rods being loosely connected with the short crank-shafts and adjustable in height secured to the seats as shown and described.

698,995. FINE-BECKER. Broom Elevator, New York, N. Y. Filed Jan. 16, 1902. Serial No. 59,573. (No model.)

Claim.—1. In a broom-elevator, the combination of a rectangular front piece having an ear formed thereon, a rectangular back piece having an ear formed thereon, said rectangular pieces being united along their edges to form a cushion-bag and said ears being united to form a pocket, substantially as described.

2. In a broom-elevator, the combination of a rectangular front piece having an ear formed on one end, a rectangular back piece having an ear formed on one end, said rectangular pieces being united along their edges to form a cushion-bag and turned up and united by a seam to form a pocket-pocket, and said ears being united by a seam to form a double-pocket, substantially as described.

698,996. BOLLES-PHILIP. Broom Elevator, New York, N. Y. Filed May 15, 1901. Serial No. 60,300. (No model.)

Claim.—1. A belt-finder, comprising a casing having orifices respectively in communication with the feed-water supply, the boiler supply and the boiler steam-pressure, an orificed barrel arranged to turn in the casing and to communicate the orifices thereof, and a stationary barrel arranged in the first-mentioned barrel and orificed in conformity with the orifices in the casing.

2. A belt-finder, comprising a casing having orifices respectively in communication with the feed-water supply, the boiler supply, and the boiler steam-pressure, an orificed barrel arranged to turn in the casing, and a second orificed barrel stationary within the first-mentioned barrel and having its orifices in conformity with the orifices in the casing, said sec-

ond barrel having partitions forming it into separate compartments, for the purpose specified.

3. A belt-finder, having a casing adapted to communicate with the feed-water supply, the boiler steam-pressure and the boiler-feed, a barrel arranged to turn in the casing and having orifices communicating alternately with the feed-water supply, the boiler-pressure and the boiler-feed, said barrel having the orifices therein arranged spirally around it for the purpose specified, and a second barrel held stationary within the first barrel and having openings communicated by the moving barrel, each opening of the stationary barrel being respectively related to the feed-water supply, the boiler-supply and the boiler steam-pressure.

4. A belt-finder having a casing adapted to communicate with the feed-water supply, the boiler steam-pressure and the boiler-feed, a barrel arranged to turn in the casing, and having orifices communicating alternately with the feed-water supply, the boiler-pressure and the boiler-feed, said barrel having the orifices therein arranged spirally around it for the purpose specified, and a second barrel held stationary within the first barrel, and having openings covered and uncovered by the first barrel, each opening of the second barrel being respectively related to the feed-water supply, the boiler-supply and the boiler steam-pressure, and transverse partitions fastened in the second barrel and between the openings thereof.

698,997. BEE. Broom Elevator, New York, N. Y. Filed Jan. 16, 1902. Serial No. 59,574. (No model.)

Claim.—1. A belt-body comprising a pair of insular bands having a transverse fulcrum, an elastic portion interposed between said bands, a back piece held in place by and adapted to cover said elastic portion, and a pair of clamps adapted to be secured to the free ends of said bands, the meeting edges of said clamps being disposed at such an angle as to draw the meeting edges of the belt downward, forming a point.

2. A belt-body comprising a pair of insular bands having a transverse fulcrum formed by longitudinal plates or folds, an elastic intermediate portion interposed between said bands, and a pair of clamps adapted to be secured to the free ends of said bands, the meeting edges of said clamps being disposed at such an angle as to draw the meeting ends of the belt downward, forming a point.

3. A belt-body comprising a pair of insular bands having a transverse fulcrum formed by longitudinal plates or folds, an elastic intermediate portion interposed between said bands, a back piece adapted to cover said elastic portion, loops carried by said back piece adapted to cover and guide said elastic portion, and a pair of clamps adapted to be secured to the free ends of said bands, the meeting edges of said clamps being disposed at such an angle as to draw the meeting ends of the belt downward, forming a point.

698,998. HUNTS MARKING AND ERASING INSTRUMENT. HUNTS & LORAN, New York, N. Y. Filed May 14, 1901. Serial No. 60,301. (No model.)

Claim.—The sheet having lines and dotted lines alternately drawn on its face, said lines and dotted lines being marked with the same letters and so spaced as to represent the intervals of the distance scale of Gouge and having the extended portions of said lines marked with the same letters and having short marks drawn between the proper lines and dotted lines to represent the sharp and fine tones of the scale, said sheet being provided with a lip-catch having lines drawn across its face and so spaced as to represent the major-key combination of intervals and marked with the symbols representing said intervals, said sheet being provided

also with the same at right angles and marked with the kinds of notes and rests as regards time, said sheet also being provided with a lip-catch D, in combination with the marking-surface and suitable means for holding said marking-surface in position relative to said sheet and admitting relative movement of said surface and sheet past and underneath the face of said sheet substantially as shown and described.

698,999. WINDMILL. GRANT & LOVELL, Boston, Mass. Filed Feb. 8, 1902. Serial No. 59,584. (No model.)

Claim.—1. In a windmill, the combination of a rotary frame, an oscillatory frame mounted on the rotary frame, a wind-wheel concentrically mounted on the oscillatory frame, whereby its weight will resist any oscillatory movement of the same, and gearing arranged on the said frame for communicating motion from the wind-wheel, one of the gears being arranged to partially revolve around the other, substantially as and for the purpose described.

2. In a windmill, the combination of a main frame, an oscillatory frame mounted on the main frame, a wind-wheel concentrically mounted on the oscillatory frame, a gear mounted on the main frame, and a pinion connected with the wind-wheel and carried by the oscillatory frame and meshing with the said gear and adapted also to revolve partially around the main frame, whereby the oscillatory frame will be swung upward and caused to lift the wind-wheel, substantially as described.

3. In a windmill, the combination of a main frame, an oscillatory frame mounted on the main frame, a wind-wheel arranged concentrically on the oscillatory frame, gears mounted on the said frame, the gear of the oscillatory frame being arranged to partially revolve around the other gear, whereby the oscillatory frame will be caused to lift the wind-wheel, and an adjustable weight carried by the oscillatory frame, substantially as and for the purpose described.

4. In a windmill, the combination of a main frame, an oscillatory frame of approximately elliptical shape mounted on the main frame and arranged normally in an upright position and provided with an adjustable weight, a wind-wheel concentrically mounted on the oscillatory frame and arranged below the pivotal point thereof, and gearing connected with the said frame, one of the gears being arranged to revolve partially around the other, substantially as described.

5. In a windmill, the combination of a rotary frame having arms at opposite sides, an oscillatory frame pivotedly connected to the said arms and supported by the same, a wind-wheel concentrically mounted on the oscillatory frame, and gears arranged between the said frame and mounted on the same for communicating motion from the wind-wheel to the device to be operated, one of the gears being arranged to revolve partially around the other, substantially as described.

6. In a windmill, the combination of a frame, an oscillatory frame mounted on the said main frame, a wind-wheel carried by the oscillatory frame and arranged concentrically of the main, pinions located at opposite sides of the oscillatory frame and connected with the wind-wheel, and internal gears mounted on the main frame and supporting and receiving the pinions, the latter being adapted to revolve partially around the internal gears, substantially as described.

7. In a windmill, the combination of an approximately U-shaped main frame having its sides provided with inner depending arms, an oscillatory frame pivotedly connected with the arms and arranged in an upright position, a wind-wheel mounted on the lower portion of the oscillatory frame, short shafts journaled on the sides of the main frame, pinions connected with the wind-wheel and located between the frames, internal gears mounted on the short shafts and receiving the pinions, and eccentric devices arranged at the outer ends of the short shafts, substantially as described.

8. In a windmill, the combination of a rotary frame, having a U-shaped upper portion and provided with a slotted stem, an oscillatory frame arranged within the rotary frame, a wind-wheel concentrically mounted on the oscillatory frame, short shafts mounted on the rotary frame at opposite sides thereof, gearing connecting the short shafts with the wind-wheel, the approximately U-shaped vertically-oscillating frame extending through the slotted stem and designed to be connected with a pump-rod, and eccentric connections between the sides of the reciprocating frame and the short shafts, substantially as described.

698,800. SAFETY-ENVELOP. CHARLES E. HARR, Haddam, Conn. Filed Oct. 28, 1904. Serial No. 73,781. (No model.)

Claim.—1. In a safety-envelop, a front piece and a back piece, the two when the envelop is formed lying in contact and constituting the closure, side flaps for retaining said front and back pieces in position, and a closing-flap upon each of said front and back pieces, said flaps when the envelop is formed lying one against the other and having adhesive material on the face thereof, the outer flap having its sealing-edges projecting beyond the edge of the inner flap, whereby the two gummed flaps are adapted to be maintained together.

2. In a safety-envelop, a front piece and a back piece, the two when the envelop is formed lying in contact and constituting the closure, inner side flaps attached to one piece and adapted to be sealed against the inner side of the other piece, outer side flaps attached to the other piece and adapted to be sealed against the outer side of the first piece, and a closing-flap upon each of said front and back pieces, said flaps when the envelop is formed lying one against the other and having adhesive material on the face thereof, the outer flap having its sealing-edges projecting beyond the edge of the inner flap, whereby the two gummed flaps are adapted to be maintained together.

3. In a safety-envelop, the body portion having an aperture therein for the reception of a sealing medium, an apertured disk underlying and surrounding said aperture, a closing-flap adapted, when closed, to partially overlap said aperture, in combination with a confining-drop for the contents adapted to underlie said aperture and form the base for the reception of the sealing medium.

698,801. SEAL. CHARLES E. HARR, Haddam, Conn. Filed Oct. 28, 1904. Serial No. 73,782. (No model.)

Claim.—1. A seal for envelopes, documents, and the like, consisting of two parts: a top surface of fabric, and a relatively thicker under surface of plastic material.

2. A seal for envelopes, documents, and the like, consisting of two parts: a top surface of fabric, and a relatively thicker under surface of adhesive plastic material.

698,802. MANIPULATING DEVICE. CHARLES E. HARR, Haddam, Conn. Filed Oct. 28, 1904. Serial No. 73,783. (No model.)

Claim.—1. In a manipulating device, a table or support, a web of carbon carried by said support, and

passing over a portion of the surface of said table or support, and a plate lying in the path of travel of one edge of said carbon and over which said edge of the carbon will travel, said plate being raised slightly from the table-surface to permit the passage thereunder and under the carbon of a sheet of paper to be manipulated.

2. In a manipulating device, a casing forming a table, a web of carbon carried by said casing and passing through slots in said casing over a portion of said table, strips attached to said table adjacent to said slots and over which said carbon passes to maintain it slightly above the table throughout its width, and a plate mounted on said strips and lying in the path of travel of one edge of said carbon and over which said edge of the carbon will travel, said strips serving to raise said plate slightly above the table-surface to permit the passage thereunder and under the carbon of a sheet of paper to be manipulated.

3. In a manipulating device, a table or support, a web of carbon carried by said support, and passing over a portion of the surface of said table or support, a sheet of protecting material overlying said carbon where it passes over the table-surface, and means for detachably retaining said sheet in fixed position.

698,803. SHEET-FLOW. JAMES HARRIS, Chicago, Ill. Filed Nov. 2, 1904. Serial No. 73,784. (No model.)

Claim.—1. In a plow, the combination with an intermittently-pivoted stock, of a lock-bar pivoted at one end and adapted to engage intermediate of its ends a part of the stock to lock the stock in position, and means for locking the free end of said lock bar, as set forth.

2. In a plow, the combination with an intermittently-pivoted stock, of a lock-bar over which a part of the stock moves, a lock-bar pivoted at one end to the bed-bar and having a locking engagement with the part of the stock which moves over the bed-bar, and means for securing the free end of the lock-bar in position, as set forth.

3. In a plow, the combination of an intermittently-pivoted stock, and means for adjustably holding the upper end thereof, said means comprising an arc-shaped bed-bar over which a part of the stock moves, a lock-bar pivoted at one end and releasably engaged with said part of the stock, to hold it, and a lock for holding the lock-bar in active position.

4. In a plow, the combination with the beam, of a stock in two parts lying one on each side of the beam and fastened rigidly together, a member carried rigidly on the outer side of the beam to which member the stock is pivoted, and a pivoted locking-bar for engaging a connecting member of the stock to adjustably hold the same.

5. In a plow, the combination of a stock-bar lying under the plow-beam, and a means at each end of the stock-bar for supporting it from the beam and adjusting it vertically, said means being adjustably connected to the stock to permit the stock to be adjusted horizontally.

6. In a plow, the combination of a stock-bar lying horizontally under the beam, means for adjusting the front end of the stock vertically and horizontally, a leg at the rear part of the stock to which the stock is con-

tested to be adjustable horizontally, and a means on the beam for holding the leg and allowing it vertical adjustment.

7. In a plow, the combination with the beam, of a brace attached thereto and projecting downward and forward therefrom, a stock pivotedly attached to the beam and projecting up to the beam, a means on the beam for adjustably holding the stock, a shoe, a link adjustably connected to the front end of the shoe and to the beam, and a leg connecting the rear end of the shoe with the beam.

8. In a plow, the combination with a beam, and an intermittently-pivoted stock carried by the beam, said stock being provided at its upper end above the beam with a cross-pin, of a pivoted locking-bar having a notched under face to engage the cross-pin of the stock, and means for locking the said bar in position.

9. In a plow, the combination with a beam provided with a downwardly and forwardly projecting brace, of a stock pivoted to the beam, said stock being formed of two parts connected together by bolts one on each side of the beam, a bed-bar secured upon the upper face of the beam and having a curved upper face, a locking-bar pivoted to the bed-bar and having a plurality of notches in its under face for engaging one of the connecting-bolts of the stock, and a catch for engaging the free end of the locking-bar to lock it in position.

698,804. FINGER-CROWDER. FREDERICK HARRIS, Troy, N. Y. Filed Sept. 20, 1904. Serial No. 73,785. (No model.)

Claim.—1. A paper-making machine, having a wheel mounted to turn in the cylinder-vat and arranged to cross the fibers in the pulp previous to the latter passing to the cylinder; the said wheel having wings gradually decreasing in height from the middle of the wings to the ends thereof, as set forth.

2. In a paper-making machine, the combination of a vat having a feed-inlet, a cylinder, and a fiber-crossing wheel revolvably mounted in said vat between the cylinder and the feed-inlet, said wheel provided with longitudinally-tapering blades which are arranged to throw pulp fibers in crossing paths within the vat.

3. A paper-making machine, provided with a cylinder-vat and a wheel extending transversely in the vat and mounted to rotate at a higher rate of speed than the cylinder, the wheel being located between the cylinder and the inlet, and the wheel having radial wings diminishing in height from the middle of the wings toward the ends thereof, as set forth.

4. In a paper-making machine, the combination with a vat, and a cylinder, of a fiber-crossing wheel mounted within said vat and revolvable in an opposite direction to, and at greater peripheral speed than said cylinder, said wheel having longitudinally-tapered blades arranged to direct pulp fibers in crossing paths in the vat.

698,805. GUINING DEVICE FOR TROLLEYS. JOHN A. HARRIS, Chicago, Ill. Filed Oct. 28, 1904. Serial No. 73,786. (No model.)

Claim.—1. In a device of the class specified, a supporting frame, a trolley-wheel carried thereby, a guine carried on the axle of the trolley-wheel and having oppositely-projecting legs extending over the edge of the wheel, said legs being spaced for a distance sufficient to permit of the free movement of the counterbalancing-weights between them, and counterbalancing-weights secured to or formed integral with said guine at a point below their pivotal ends.

2. In a device of the class specified, the combination of the oppositely-disposed and connected side plates, a shaft or axle mounted therein, a trolley-wheel journaled on said shaft, guards pivoted on said shaft and

having oppositely-extended leaped portions projecting over and inwardly beyond the rim of the wheel and serving to prevent the wheel from riding up over the rim of said wheel, and counterbalancing-weights secured to or formed integral with said guards at points below the shaft or axle, substantially as specified.

3. In a device of the class specified, the combination of the oppositely-disposed and connected side plates, a shaft or axle mounted therein, a trolley-wheel journaled on said shaft at a point between the side plates, guards mounted on said shaft at a point outside the plates, said guards having oppositely-extended leaped portions projecting over the edges of the trolley-wheel and spaced for a distance greater than the diameter of the trolley-wheel, stops formed on said side plates for limiting the oscillating movement of the guards, and depending counterbalancing-weights secured to or formed integral with said guards at points below the shaft or axle, substantially as specified.

4. In a device of the class specified, a frame comprising oppositely-disposed and connected plates, a shaft carried thereby, a grooved trolley-wheel journaled on said shaft, guards pivoted on the shaft at points outside the plates, said guards having oppositely-extended leaped portions projecting over the edges of the trolley-wheel and spaced for a distance greater than the diameter of the trolley-wheel, a bifurcated arm pivoted between the plates at a point at the rear of the trolley-wheel, a depending leg or finger on said guard or arm, and a stop-pin adapted to support the bifurcated arm in one position and to form a stop for engagement with said leg or finger when the arm is in the opposite position, substantially as specified.

698,806. ACETYLENE-GAS GENERATOR. PAUL F. V. HERRMANN, Jean F. Herr, and Jean Herr, Philadelphia, Pa. Filed July 27, 1904. Serial No. 73,787. (No model.)

Claim.—1. In an acetylene-gas apparatus, a generator adapted to contain water, said generator comprising a charging-chamber and a generating-chamber, a carbide-holder having a hinged lid normally locked to prevent the admission of water to the holder, a hollow rod connected with the holder and projecting through the top of the generator, said rod serving to move the holder into the charging-chamber for charging and into operative position in the generating-chamber, and means operative through said rod for unlatching and raising the lid of the holder.

2. In an acetylene-gas apparatus, a generator adapted to contain water and comprising a charging-chamber and a generating-chamber, a carbide-holder having a hinged lid normally locked to prevent the admission of water to the holder, a hollow rod connected with the holder and projecting through the top of the generator, said rod serving to move the holder into the charging-chamber for charging and into operative position in the generating-chamber, and a chain operative through said rod for unlatching and raising the lid of the holder.

3. In an acetylene-gas apparatus, a generator adapted to contain water, a vertical partition dividing said chamber into a charging-chamber and a generating-chamber, a carbide-holder having a lid normally closed to prevent the admission of water, a hollow rod connected with the holder and projecting through the top of the generator, and means operative through said rod for raising the lid of the holder.

698,807. PARTY-LINE TELEPHONE APPARATUS. GEORGE HARRIS, Copenhagen, Denmark. Filed Sept. 20, 1904. Serial No. 73,788. (No model.)

Claim.—1. A party-line telephone apparatus, comprising a com-

log-relays for establishing talking-circuits between the stations, disconnecting-relays for disestablishing said circuits, blocking-relays for cutting out divers stations from said circuits, and auxiliary blocking-relays for cutting other stations into said circuits.

2. A party-line telephone apparatus, comprising connecting-relays for establishing talking-circuits between stations, disconnecting-relays for disestablishing said circuits, blocking-relays for cutting out divers stations from said circuits, auxiliary blocking-relays for cutting said divers other stations into said circuits, and means controllable at will whereby a calling subscriber can simultaneously render his own blocking-relay inactive and give warning to divers stations that the line is busy.

698,808. ACETYLENE-GAS GENERATOR. GEORGE J. HENNINGER, Rockaway Beach, N. Y. Filed Nov. 13, 1906. Serial No. 54,382. (No model.)

Claim.—1. A generating-tank, a hopper communicating therewith by a suitable passage, and a valve for closing said passage and consisting of a segment of a roller, provided with a diamond-shaped opening adapted to register with said passage.

2. A generating-tank provided with an inclined bottom, a hopper communicating with said tank by a suitable passage, a valve for closing said passage and consisting of a segment of a roller, said valve provided with a diamond-shaped opening adapted to register with said passage, and a gas-holder connected to said segment for operating the same.

3. The combination of a part having a feed-opening for the carbide, a pivoted valve having a curved face controlling said feed-opening, said curved face having an opening provided with a tapering end and adapted to register with said feed-opening.

698,809. LIQUID-CONTAINER. HENRY E. HYMAN, Covington, Ky. Filed Jan. 20, 1908. Serial No. 54,494. (No model.)

Claim.—A liquid-container, comprising a vessel, a jacket surrounding the vessel and having its lower end projecting below the bottom of the vessel, a supporting-ring secured to the inner wall of the jacket and adapted to support the vessel at a point above the lower end of the jacket, bands secured to the exterior of the jacket at its upper and lower ends, vertically-disposed strips connecting the said bands, said strips having their lower ends bent under the lower edge of the jacket and the inner supporting-ring and thence upwardly against the inner face of the supporting-ring, thence over the upper edge of the supporting-ring and thence upwardly parallel with the jacket and confined between said jacket and the vessel, substantially as set forth.

698,809.

698,810. BRAKE FOR RAILWAY-CARS. WILLIAM E. HEDDER, Belvidere, N. J., assignor of two-thirds to Joseph E. Wilson, Henry E. Harris, Charles E. Harris, and Robert E. Harris, Belvidere, N. J. Filed Feb. 21, 1904. Serial No. 44,260. (No model.)

Claim.—In a truck-brake for railway-cars, the shoes, the brake bars or links having a pivotal connection with said shoes, and with the truck-frame, the toggle-levers having a pivotal connection with said shoes, and with the truck-frame, and means for operating said toggles, substantially as specified.

698,811. MAGNETIC SEPARATOR. JOHN E. A. McFARLANE, Dunedin, New Zealand. Filed Dec. 1, 1901. Serial No. 54,599. (No model.)

Claim.—A magnetic separator, a pulley consisting of a core and a shell surrounding the same and integral therewith, a magnetic coil wound upon said core and extending substantially to the inner face of said shell, a shaft extending through said core for supporting and rotating the pulley, suitable electrical connections for said coil, insulated means for driving the pulley in rotation, a belt, supported by said pulley and adapted to receive and separate the material, means for supplying the material to the belt, and means for operating said pulley in a rotary direction and to impart a continuous movement to the pulley while it is rotating.

698,812. ADJUSTABLE FIBER-BOX FOR STOVES. JAMES P. HANLEY, Cambridge, Wash. Filed Feb. 8, 1908. Serial No. 4,682. (No model.)

Claim.—1. In a fiber-box, a back consisting of a main central portion, side portions horizontally adjustable thereon, and top portions having their outer ends vertically adjustable on the side plates and their inner ends vertically and horizontally adjustable on the main central portion, substantially as described.

2. In a fiber-box, a back consisting of a main central portion, side portions horizontally adjustable thereon, top portions having their outer ends vertically adjustable on the side plates and a vertically-adjustable clip on said main central portion and carrying a pin adapted to engage horizontal slots in the top portions, whereby the inner free ends of the top portions are vertically and horizontally adjustable on the central portion, substantially as described.

3. In a fiber-box, an end plate comprising a main lower section having a grab-joint, a secondary lower section horizontally adjustable on the main section, a top section between the two lower sections and vertically adjustably connected to the lower main section and a second top member horizontally adjustable on the first top member substantially as described.

4. In a fiber-box, an end plate comprising a main lower section having a grab-joint, a secondary lower section horizontally adjustable on the main section, a top section between the two lower sections and vertically adjustably connected to the lower main section, a second top member horizontally adjustable on the first section, and a pronged leg carried thereby adapted to receive a member carried by the back, substantially as described.

5. In a fiber-box, a front comprising an upper and a lower part interlocking with each other, outwardly-extending ears carried by the ends of said upper section and having vertical slots therein, outwardly-extending ears carried by the lower section and overlapping the ears of the upper section and having a vertically-arranged row of openings, a covering-plate having a series of vertically-arranged openings, a back carried by the outer end of said plate, and securing-bolts passing through the openings in the lower section, the slots in the upper section and through any of the desired openings in the covering-plate, substantially as described.

698,813. GLUTEN-PULLEY. THOMAS J. O'BRIEN and ROBERT L. ALLEN, Cuba, N. Y. Filed May 17, 1901. Serial No. 54,704. (No model.)

Claim.—The combination of the shaft, a clutch-disk fastened thereto and rotated thereby, a pulley having a hollow web receiving the clutch-disk and web having a hub on each side of the disk, the hubs being loosely mounted on the shaft, whereby the entire weight of the pulley is sustained by the shaft, a clutch member carried by the pulley and working with the periphery of the disk, and means for operating the clutch member.

698,814. RAIL-SHOOT CLAMP. PATRICK O'KEEFE and JOHN E. WHELAN, Orange, Mass. Filed Aug. 21, 1901. Serial No. 73,990. (No model.)

Claim.—1. The combination with a rail, of a block adapted to rest against the web thereof between the head and flange and an angular clamp-plate adapted to embrace said block and base of the rail, and a plate attached to the projecting end of said angular clamp-plate having a bolt passing therethrough to bear upon the rail, substantially as shown and described.

2. The combination with a rail, of a block adapted to fit against the web of said rail between the head and base, an angular clamp-plate adapted to embrace the said block and base of the rail and project beyond said base, a plate having its end projected through the projecting end of the clamp-plate, the opposite end of said plate having an aperture; a bolt adapted to pass through said aperture, and the nut arranged upon the bolt between the plate and head of bolt, substantially as shown and described.

3. The combination with an angular clamp-plate or bar, one end having teeth, the other end having a rectangular-shaped opening, of a clamp member, having a threaded aperture at one end and a shouldered leg at the other end, and a bolt and nut not all arranged substantially as shown and described.

698,815. GRINDING-MACHINE. BLAKE S. SUMNER and HENRY A. PARKER, Milton, Pa., assignors to Samuel J. Osipow and Sam. H. Milton, Pa. Filed Feb. 21, 1908. Serial No. 54,180. (No model.)

Claim.—1. In a grinding device, a cylindrical holder adapted to hold a cylindrical bit during the process of grinding, and a guide for the head of said bit, substantially as described.

2. In a grinding device, a cylindrical holder adapted to support a cylindrical bit having a curved head, during the process of grinding and an adjustable guide for the head of said bit, substantially as described.

3. In a grinding device, a cylindrical bit-holder, a semi-circular rest-bar slidingly mounted in a transverse slot in said holder, a guide-pin mounted in said rest, and means for operating said rest, substantially as described.

4. In a grinding device, the combination with an emery-wheel, of an adjustable arm bearing a clamp, a cylindrical holder provided with a spindle embraced by said clamp, and an adjustable guide mounted on said holder, substantially as described.

698,816. GARMENT-STRETCHER. JAMES FERGUSON, Youngstown, Ohio. Filed Jan. 20, 1908. Serial No. 54,771. (No model.)

Claim.—1. In a trouser-stretcher, the combination with the supporting means for one end of the trousers, of a stretching-clamp comprising a pair of gripping-jaws, a clamp-adjuster carried by one of the jaw members and having means for the clamp-adjuster, substantially as set forth.

2. In a tresser-stretcher, the combination with supporting means for one end of the tresser, of a stretching-clamp comprising a pair of pivotally-connected lever members having gripping-jaws, a clamp-adjuster carried by one of the lever members and co-operating with the other member to effect a closing of both jaws, said clamp-adjuster also constituting the stretching element and holding means for the clamp-adjuster, substantially as set forth.

3. In a tresser-stretcher, the combination with supporting means for one end of the tresser, of a stretching-clamp comprising a pair of lever members pivotally connected and provided with opposed gripping-jaws, and a clamp-adjuster slidably mounted upon one of the lever members co-operating with the other member to effect a closing of the jaws, said clamp-adjuster also constituting a stretcher element and holding means for the clamp-adjuster, substantially as set forth.

4. In a tresser-stretcher, the combination with a base, and a holder for one end of the tresser supported on the base, of the stretching-clamp comprising pivotally-connected lever members having opposed gripping-jaws, and a clamp-adjuster mounted upon one of the lever members and co-operating with the other member to effect a closing of the jaws, said clamp-adjuster also being engaged with the base to hold the tresser stretched, substantially as set forth.

5. In a tresser-stretcher, a supporting-base having a series of locking-notches, a holder supported upon the base and having means for holding one end of the tresser, and a stretching-clamp comprising a pair of lever members pivotally connected and having opposed gripping-jaws at one side of the pivotal point, one of said lever members being provided at the opposite side of the pivotal point with a guide-frame, and the other member being provided with an inclined pressure member or arm extending within the plane of the guide-frame, and a clamp-adjuster in the form of an open link slidably mounted upon said guide-frame and adapted to engage the notches of the base, said adjuster having a barworking against the said pressure-arm of one of the lever members, substantially as set forth.

6. In a tresser-stretcher, the combination with a base and a holder for one end of the tresser, of a stretching-clamp comprising lever members formed of wire bodies pivotally joined, said lever members being formed at one side of their pivot with open gripping-jaws, one of said lever members being further provided at the opposite side of the pivot with an open guide-frame and the other lever member being also further provided with an outwardly-extending angled arm having an inwardly-extended inclined pressure element, and an open link having guide-eyes slidably engaging the said guide-frame and also having a slide-bar co-operating with said pressure element, substantially as set forth.

7. In a tresser-stretcher, the combination of a stretcher-bar having a series of notches, a fixed holder mounted upon the bar and having means for engaging the upper end of a pole of tresser and preventing longitudinal displacement thereof, and a stretching-clamp comprising a pair of pivotally gripping-jaws, and a slidable clamp-adjuster carried by one of the jaw members and co-operating with the series of notches of the stretcher-bar, substantially as set forth.

698,817. TRESSER-STRETCHER. ERIC L. FINE, Toronto, Canada. Filed Nov. 22, 1901. Serial No. 54,121. (No model.)

Claim.—1. In a tresser-stretcher, a movable signal-arm, a lamp showing in the direction from which a train is moving, and spectacle connected with the signal-arm so that they move in front of the lamp in accordance with the position of the signal-arm, in combination with means for receiving the light from the side of the lamp and throwing it in the direction in which the train is moving, and supplemental spectacle movable with the signal-arm to cause the light thrown in the direction of the train's motion to display the same signal as is shown by the light showing in the other direction, substantially as described.

2. In a train-order signal, a movable signal-arm, a lamp showing in the direction from which a train is moving and also laterally, and spectacle connected with the signal-arm so that they move in front of the lamp in accordance with the position of the signal-arm, in combination with means for receiving the light from the side of the lamp and throwing it in the direction in which the train is moving, and supplemental spectacle movable with the signal-arm to cause the light thrown in the direction of the train's motion to display the same signal as is shown by the light showing in the other direction, substantially as described.

3. In a train-order signal, a movable signal-arm, a lamp showing in the direction from which a train is moving and also laterally, and spectacle connected with the signal-arm so that they move in front of the lamp in accordance with the position of the signal-arm, in combination with means for receiving the light from the side of the lamp and throwing it in the direction in which the train is moving, and supplemental spectacle movable with the signal-arm to cause the light thrown in the direction of the train's motion to display the same signal as is shown by the light showing in the other direction, substantially as described.

4. In a train-order signal, a movable signal-arm, a lamp showing in the direction from which a train is moving and also laterally, and spectacle connected with the signal-arm so that they move in front of the lamp in accordance with the position of the signal-arm, in combination with means for receiving the light from the side of the lamp and throwing it in the direction in which the train is moving, and supplemental spectacle movable with the signal-arm to cause the light thrown in the direction of the train's motion to display the same signal as is shown by the light showing in the other direction, substantially as described.

5. In a train-order signal, two movable signal-arms governing lights moving in opposite directions; a lamp adapted to show light in each direction and also to each side; and spectacle connected to the signal-arms so that they move in front of the lamp in accordance with the position of the signal-arms, in combination with means for receiving the light from the sides of the lamp and directing it respectively in opposite directions; and supplemental spectacle movable with the signal-arms so that the light from the side of the lamp thrown in the direction of motion of any given train may be caused to display the same signal as is shown by the main light in the opposite direction, substantially as described.

698,818. TYPE-WRITING MACHINE. WILLIAM P. WHEELER, New York, N. Y. Filed May 29, 1901. Serial No. 54,122. (No model.)

Claim.—1. A movable type-wheel-carrying frame, a gear adapted when operated to impart movement to said type-wheel, a step-arm, a segment connected with the arm, a pin engaging said segment for operating it, and means for arresting the movement of said arm when operated by the segment.

2. A pin, a type-wheel-carrying frame made to swing or rock toward the pin for printing a frame-supporting shaft extended across the machine above the pin, for allowing the wheel to print or strike down onto the pin; a rotary step-arm to which the type-wheel is geared, keys for actuating the wheel, and steps for said arm made separate from the keys substantially as described.

3. A vibrating type-wheel provided with a pin, a longitudinally-adjustable shaft for rotatably supporting the wheel, a step-arm, a segment connected with the step-arm and engaged by said pin, and steps for the said arm, substantially as described.

4. A vibrating type-wheel shaft, a sleeve on the shaft, pin on the sleeve, mechanism substantially as described for engaging one of the pins to rotate the sleeve, a segment provided with a step-arm and engaged by the other pin, and steps for the arm substantially as described.

5. A vibrating frame, a type-wheel shaft carried by the frame, a sleeve on the shaft, pin on the sleeve, mechanism substantially as described for engaging one of the pins to rotate the sleeve, a segment provided with a step-arm and engaged by the other pin, and steps for the arm substantially as described.

6. A vibrating frame, a transverse supporting-shaft for the frame, a type-wheel shaft carried by said frame, a pin carried by said shaft, a segment engaged by the pin and provided with a step-arm, and steps for the arm substantially as described.

7. A vibrating type-wheel having a pin, a transverse shaft for supporting the wheel and pin, a segment provided with a step-arm and mounted independently of the type-wheel and engaged by the pin and steps for the arm substantially as described.

8. A vibrating type-wheel-carrying frame, a step-arm mounted independently of the frame and geared to the wheel, and steps for said arm, substantially as described.

9. A vibrating type-wheel-carrying frame, a step-arm mounted independently of the frame, a gear operating said step-arm and connecting it with the wheel, said gear being braked or cut to remain permanently in mesh and allow the wheel to rock to the pin while the step-arm remains at rest, substantially as described.

10. A vibrating type-wheel frame, a shaft for supporting the said frame, a type-wheel carried by the frame, a rotary step-arm to which said wheel is geared, keys for actuating the wheel and frame, and step-pins made separate from the keys for actuating the arm substantially as described.

11. A type-writing machine provided with a type-wheel, a shoulder-pin and arm for rotating the wheel, and key-actuated lever or bell lever below and linked or joined to the arm for actuating the latter substantially as described.

12. A type-writing machine provided with a type-wheel, arm for rotating the wheel, actuating lever or bell lever below and linked to the arm, and keys for actuating the lever substantially as described.

13. A type-writing machine provided with a type-wheel, arm for rotating the wheel, actuating lever below said arm and linked to the latter, and key-levers having their inner ends made to pass under the actuating-lever to lift the latter substantially as described.

14. A vibrating type-wheel frame and a wheel and pin carried by the frame, combined with a segment having a step-arm, steps for the arm, a link for preventing premature tilting of the frame, and keys for actuating the steps and freeing the link substantially as described.

15. A type-writing machine provided with a vibrating type-wheel frame having a type-wheel and pin, a step-arm geared to the pin, steps for the arm, keys for actuating the steps, arm and lever for rotating the wheel, and a link for preventing premature tilting of the frame, said wheel-actuating lever and link being both engaged by the inner end of the key substantially as described.

16. A type-writing machine provided with a wheel and keys, a driving-arm for the wheel, a step-arm separate from the driving-arm provided with a braked or limited edge and with eyes, combined with pin, said arm being made to engage or lift the eyes to said pin substantially as described.

17. A type-writing machine provided with a wheel and keys, step-pins having a spring or yielding support on the keys, and a step-arm made to ride over or displace the pin and to be locked on the pin or to turn of the latter substantially as described.

18. A type-writing machine provided with a wheel and keys, step-pins actuated by the keys and a step-arm having a level or ladder made to swing clear of and to ride or slide over the pin and an eye or locking portion for the engagement of the pin substantially as described.

19. A type-writing machine provided with a rotary type-wheel and a step-arm for the wheel, combined with pins made to arrest and lock the step-arm against rotation and a toothed disk engaging locking-pawl 45° for holding the wheel against rotation, said step-arm being made to rest normally clear of the pin substantially as described.

698,819. AUTOMATIC CAR-BRAKE. ALBERT W. RICE, Chicago, Ill. Filed July 11, 1901. Serial No. 54,123. (No model.)

Claim.—1. In a device of the class described, the combination with a car having a car-coupling capable of longitudinal movement, of a transverse lever pivoted on the car and designed to be connected at one end with the brake-opening connection, and means for connecting either the inner or outer arm of the lever with the brake mechanism, whereby the parts are arranged either for braking or holding a car or train, substantially as described.

2. In a device of the class described, the combination with a car provided with a car-coupling capable of longitudinal movement, of a transverse lever pivoted between its ends on the car, means for connecting the outer end of the lever with a car-brake, a coupling-pole connected to the car-coupling, the longitudinal bar connected to the inner arm of the transverse lever and detachably connected to the coupling-pole, and a chain connected with the outer arm of the lever and provided with means for detachably engaging the coupling-pole, substantially as described.

3. In a device of the class described, the combination with a car having a car-coupling capable of longitudinal movement, of a brake-rod, a flexible connection extending from the outer end of the brake-rod, a transverse lever pivoted between its ends and connected to the said flexible connection, a coupling-pole connected to the car-coupling and provided with a bracket or bar, a bar pivoted to the inner end of the lever and detachably connected to the bracket or bar of the coupling-pole, and means for detachably connecting the outer end of the lever with the coupling-pole, substantially as described.

698,820. SHOCK-GEAR. ALBERT RUSSELL, Baltimore, Md. Filed Dec. 2, 1901. Serial No. 54,124. (No model.)

Claim.—1. The combination in a shock-arm, of the adjusting plate, one of which is arranged to overlap the other at an angle, said plates being provided with openings for the studs and fastening-ends, the connecting-bracket composed of the main plate and the threaded studs hinged to the main plate at the opposite ends of the latter, the hinge-brackets on the main plate being arranged entirely in advance of the outer surface of the main plate, whereby the latter may rest flat throughout its length against the surface of the glass and the nuts turned on the said studs within the openings in the glass plate, substantially as set forth.

2. A fastening or connecting bracket for shock-arms comprising the main plate, the threaded end at one end of the main plate, and the threaded end hinged to the main plate at the opposite end of the latter, whereby it may be turned into alignment with or at any desired angle to the main plate, substantially as set forth.

3. In a shock-arm the improved fastening or connecting bracket for holding the adjusting plate of the case consisting of the main plate, and the threaded studs hinged at one end to the main plate at the opposite ends of the latter, whereby they may be turned into alignment with or at any desired angle to the main plate, substantially as set forth.

4. A fastening device for glass plates comprising a plate and a stud hinged thereto at the end of said plate whereby the fastening can be applied to connect two plates of glass at any desired angle to each other with the stud extending at a right angle to the plate of the glass plate to be fastened, substantially as set forth.

8. A fastening or connecting bracket for above-mentioned, comprising the main plate, and a threaded section hinged at one end to the main plate at one end of the latter, whereby the said threaded section may be adjusted into alignment with or at an angle to the main plate, substantially as set forth.

698,891. **SOLE.** FRANK BROWNE and WILLIAM J. BROWNE, Fall River, Mass. Filed Aug. 21, 1899. Serial No. 73,595. (No model.)

Claim.—1. An apparatus of the kind described, comprising a jumper, a reversible member connected therewith, and a buffer engaging said reversible member for the purpose of cushioning the upstroke of said jumper.

2. An apparatus of the kind described, comprising a jumper, a reversible roller connected therewith, and a spring-tensioned lever mounted in the path of said roller for cushioning the upstroke of said jumper.

3. An apparatus of the kind described, comprising a jumper, a reversible roller mounted thereon, a lever engaging said roller for the purpose of buffering the upstroke of said jumper, and means for adjusting the position of said lever relative to said jumper.

4. An apparatus of the kind described, comprising a jumper, a reversible member connected therewith, and a lever for engaging said reversible member and thereby buffering the upstroke of said jumper; said lever being made of interchangeable sections.

5. An apparatus of the kind described, comprising a jumper, a reversible member connected therewith, a lever engaging said reversible member for cushioning the upstroke of said jumper, said lever being provided with a curved end for the purpose of modifying the effect of said reversible member upon said lever.

6. An apparatus of the kind described, comprising a jumper, a reversible member connected therewith, a lever for engaging said reversible member and provided with a curved end for modifying the impact of said reversible member upon said lever, and means for adjusting the position of said curved end of said lever relative to the position of said jumper.

7. An apparatus of the kind described, comprising a jumper, a lever for buffering the upstroke of the same, a normally fixed disk provided with a stop for said lever, and means for causing said disk to be predetermined position, at will.

8. An apparatus of the kind described, comprising a jumper, a lever for buffering the upstroke of the same, a spring for normally cushioning said lever, and means for adjusting said lever relative to said jumper.

9. An apparatus of the kind described, comprising a jumper, a reversible member connected with the same, a lever for cushioning the upstroke of said jumper and provided with a curved end for engaging said reversible member, and means for adjusting said lever in different radial positions.

10. An apparatus of the kind described, comprising a jumper, means for guiding the same in a predetermined path, a reversible member connected with said jumper, a lever provided with a curved end, and means for adjusting said lever to predetermined radial positions, for the purpose of causing said curved end to be engaged at different angles by said reversible member.

698,892. **DOHEN FLUTE.** ROBERT P. DOHEN, Brooklyn, N. Y. Filed Sept. 20, 1899. Serial No. 74,551. (No model.)

Claim.—1. An article of manufacture, a state provided with a blow-hole and with a normally closed end, a rod-head covered upon said state, and means controllable at will for opening said end and closing said blow-hole.

2. An article of manufacture, a state provided with a normally closed cylindrical end and a normally open blow-hole, a rod-head covered upon said state, and means controllable at will for continuously closing said blow-hole and opening said cylindrical end.

3. An article of manufacture, a state provided with a rod-head, and means controllable at will for opening and closing pneumatic communication between said head and said state.

4. An article of manufacture, a state provided with an open end and with a blow-hole, a rod-head detachably covered upon said state, and means controllable at will for continuously opening said blow-hole and closing said open end.

698,893. **WATER-TUBE BELLER.** EDWIN S. BELLER, Pueblo, Colo. Filed Nov. 14, 1899. Serial No. 75,311. (No model.)

Claim.—1. The combination in a water-tube boiler, of two pairs of main drums having water-tubes extending between them, with a third pair of drums smaller in diameter than the main drums and placed parallel to them, said smaller drums also having tubes whereby they are connected and being above the lower, and below the upper of said main drums, substantially as described.

2. The combination in a water-tube boiler of upper and lower main drums having tubes extending between them, with an auxiliary set of drums lying parallel to the main drums and also having tubes extending between them, said auxiliary set of drums being above the lower and below the upper of the main drums, substantially as described.

3. The combination in a water-tube boiler, of upper and lower main drums having tubes extending between them, with an auxiliary set of drums also having tubes connecting them and placed above the lower and below the upper of the main drums, said auxiliary set of drums being parallel with and connected to the main drums and of less capacity than the same, substantially as described.

4. In a water-tube boiler, the combination of two pairs of main drums, substantially vertical tubes connecting the members of each pair, a pair of auxiliary drums below the upper main drums and above the

lower main drums, said auxiliary drums being parallel to said main drums and also having substantially vertical tubes connecting them together, with a bellows supported by the lower of said auxiliary drums, substantially as described.

5. In a water-tube boiler, the combination of two pairs of main drums, water-tubes connecting the members of each pair, a pair of auxiliary drums between said pairs of main drums, and also having water-tubes connecting them, said auxiliary drums being above the lower and below the upper of the main drums, and a bellows supported by the lower auxiliary drums and extending between the tubes thereof to the upper auxiliary drums, substantially as described.

6. In a water-tube boiler, the combination of two pairs of main drums, water-tubes connecting the members of each pair, a pair of auxiliary drums between said pairs of main drums also having water-tubes connecting them, said auxiliary drums being above the lower and below the upper of the main drums and parallel to the same, and a bellows supported by the lower auxiliary drums and extending between the tubes thereof to the upper auxiliary drums, said auxiliary drums being of a diameter less than the main drums and being connected thereto, substantially as described.

7. In a water-tube boiler the combination of two pairs of main drums, a series of water-tubes of equal length connecting the members of each pair, auxiliary drums parallel to and between said main drums, also having tubes of equal length connecting them, tubes connecting the lower of the auxiliary drums with the lower main drums, and tubes connecting the upper auxiliary drums with the upper main drums, substantially as described.

8. In a water-tube boiler, the combination of a furnace, upper and lower main drums having water-tubes connecting them, auxiliary drums of smaller volume between said main drums and also having tubes connecting them, with means for causing the hot gases from the furnace to rise vertically around the tubes of the first pair of main drums and after passing between the upper main drums and the upper auxiliary drums to flow down between the tubes connecting the lower main drums and the tubes connecting the auxiliary drums, said means freely causing the gases to pass over the lower main drums and to enter a stack connected to the stack, substantially as described.

698,894. **WY.** SAMUEL WYMAN, New York City, N. Y. Filed Oct. 13, 1899. Serial No. 75,355. (No model.)

Claim.—1. In a toy of the character described, the combination of a hollow head having openings for the fingers of the hand, a covering for said head, and a slide connected to said covering and adapted to be reciprocated within said head, substantially as described.

2. In a toy of the character described, the combination of a hollow head having openings for the fingers of the hand, a slide adapted to be moved longitudinally and turned transversely within said head, and a covering attached to said head and said slide, substantially as described.

3. In a toy of the character described, the combination of a hollow head having openings for the fingers of the hand, a slide adapted to be moved within said head, a covering attached to said head and said slide, and a nose and ear projecting through their respective openings in said head and having retaining flanges or bosses and rearward extensions, said rearward extensions adapted to engage recesses or slots within said slide, substantially as described.

4. In a toy of the character described, the combination of a hollow head having openings for the fingers of the hand, a slide adapted to be moved within said head and having eye, tongue and teeth corresponding to their respective openings in the head, a covering attached to said head and to said slide, and a nose and ear projecting through their corresponding openings in said head and having retaining flanges or flanges and a rearward extension, said extensions adapted to engage slots in said slide, substantially as described.

5. In a toy of the character described, the combination of a hollow head having openings for the fingers of the hand, a slide adapted to be moved within said head and having eye, tongue and teeth corresponding to their respective openings in the head, a covering attached to said head and to said slide, and a nose and ear projecting through their corresponding openings in said head and having retaining flanges or flanges and a rearward extension, said extensions adapted to engage slots in said slide, and a link pivoted in a slot in said slide and to the tip of the nose for the purpose of closing the mouth when the slide is moved, substantially as described.

698,895. **SPONGE OR SQUEEZING MACHINE.** HENRY W. BARTON, Philadelphia, Pa. Original application filed July 6, 1899. Serial No. 75,357. Revised and this application filed Mar. 7, 1900. Serial No. 59,175. (No model.)

Claim.—1. A sponge or squeezing holder, comprising a vessel having an external shoulder and an adjacent lip, a cover applied to said shoulder and lip, an inner shoulder, and a tube suspended within the said vessel above its bottom by means of a laterally-projecting flange fitted to and resting upon the inner shoulder, the tube projecting above and below its said flange, substantially as described.

2. A vessel, having a shoulder, a rim or lip, an inner shoulder next to said rim or lip, and a tubular retainer provided with a laterally-projecting notched flange engaging the inner shoulder, the upper edge of the retainer projecting considerably above the rim or lip, and the lower tubular portion of said retainer extending toward the bottom of the vessel, substantially as and for the purpose described.

3. A vessel, having an inner shoulder next to its rim or lip, combined with a tube having a laterally-projecting notched flange resting loosely upon said shoulder, the lower portion of the tube suspended above the bottom of the vessel by said flange and the upper edge of the tube projecting considerably above the mouth of the vessel, substantially as and for the purpose described.

698,896. **BAR OR PASTERIZER FOR SUGAR.** BENJAMIN BURMAN, Boston, Mass. Filed Dec. 21, 1899. Serial No. 59,177. (No model.)

Claim.—1. A bar for sugar comprising a tank, a bar connected to the tank of said tank to be moved therewith, and a ball-bearing guide for said bar, substantially as described.

2. A bar for doors consisting of a lock, a bracket attached to the bolt of said lock, a barrier connected to said bracket to be moved with the bolt, one end of said barrier engaging a hinged keeper, substantially as described.

3. A bar for doors comprising a lock, a barrier connected to the bolt of said lock, to be moved therewith, a ball-bearing guide for the barrier, and means for locking the barrier against movement with the bolt of the lock.

4. A bar for doors comprising a lock, having a bolt to be operated by a knob or a key upon opposite sides of the lock, a barrier connected to said bolt, a ball-bearing guide for said barrier, and loops surrounding the barrier and provided with cut-aways, substantially as described.

698,827. GAS-STOVE. WILLIAM J. BRYAN, Brooklyn, N. Y.
Filed Jan. 8, 1902. Serial No. 93,847. (No model.)

Claim.—1. A gas-stove comprising a hollow base portion, vertically-arranged hollow casings mounted thereon and in communication therewith, a hollow top portion placed on said vertically-arranged hollow casings and provided with a supplemental top portion having front openings, a tubular casing arranged centrally and longitudinally in the base portion and divided by a central transverse partition, and tubular members arranged in said vertically-arranged cylindrical casings, all of which are in communication at their lower ends with the said tubular casing in the base portion and part of which are in communication with the hollow top member and the others of which pass therethrough and are in communication with the supplemental top member, substantially as shown and described.

2. A gas-stove comprising a hollow base portion, vertically-arranged hollow casings mounted thereon and in communication therewith, a hollow top portion placed on said vertically-arranged hollow casings and provided with a supplemental top portion having front openings, a tubular casing arranged centrally and longitudinally in the base portion and divided by a central transverse partition, and tubular members arranged in said vertically-arranged cylindrical casings, all of which are in communication at their lower ends with the said tubular casing in the base portion and part of which are in communication with the hollow top member and the others with the supplemental top member, said base portion being also provided with a burner-tube below said tubular casing, substantially as shown and described.

3. A gas-stove comprising a base composed of bottom and top portions, the bottom portion of the base being provided with a gas-burner tube, and the top portion of said base being provided with a horizontally-arranged tubular casing, a plurality of vertically-arranged hollow casings placed on the top base portion and in communication therewith, a horizontal hollow top portion placed on said vertically-arranged hollow casings and provided with a supplemental top portion which is placed thereon and provided with openings, vertically-arranged tubes placed in said vertically-arranged hollow casings, all of which are in communication at their lower ends with the tubular casing in the upper base portion and part of which are in communication with the top portion and others with the supplemental top portion, said tubular casing in the upper base portion being provided with a transverse partition through which one of said tubes passes substantially as shown and described.

698,828. PROCESS OF MAKING INDIGO FROM INDOL. PAUL BERN, Ludwigshafen, Germany, assignor to Badische Anilin & Soda-Fabrik, Ludwigshafen, Germany, a Corporation. Filed Sept. 24, 1901. Serial No. 74,493. (No specimens.)

Claim.—The process of manufacturing indigo which consists in treating indol with alkali-metal-potassium.

698,829. BARKING. GEORGE SCHMIDT, Berlin, Germany.
Filed Apr. 14, 1901. Serial No. 93,194. (No model.)

Claim.—1. The combination in a harness, with the saddle having a bow and a projecting pin, and the traces, of a breast-collar having straps crossed over and fixed on the pin on the bow of the saddle and connecting with the traces, substantially as set forth.

2. The combination in a harness, with the saddle having a bow and a projecting pin, and the traces, of a breast-collar having straps crossed over and fixed on the pin on the bow of the saddle and connecting with the traces, a forked strap, the body of which passes under the fore legs and the fork extends upward to the breast-collar, and straps connecting the body of the forked strap to the traces, substantially as set forth.

3. The combination in a harness with a saddle, a breast-collar, connected to the saddle, of straps fixed to the traces and fixed to the saddle, and a forked strap connected in the rear with the traces and by its forks to the breast-collar, substantially as described.

698,880. RUBBER-MAKING MACHINERY. EDWARD S. SHILLER, Columbus, Ohio. Filed July 25, 1901. Serial No. 93,691. (No model.)

Claim.—1. In a non-refillable bottle the combination with the bottle-neck having an internal annular groove or recess and vertical grooves extending above and below said annular groove or recess, of a cap fitted in the bottle-neck and having an open bottom and sides, said open sides communicating with said vertical grooves, a valve controlling the opening in the bottom of the cap, and a cap seated on top of the cap and provided with a peripheral upwardly-convex flange seated beneath the upper wall of the annular groove, substantially as described.

2. In a non-refillable bottle the combination with the neck thereof provided upon its interior with an annular groove or recess, and with an inwardly-projecting flange disposed beneath said recess, of a cap seated upon said flange, and comprising two disks connected together at their opposite sides or edges, the uppermost of said disks being impermeable and the lower one provided with a valve-opening, a valve controlling said opening and a cap seated upon said cap, and provided upon its periphery with an upwardly-convex flange seated in the annular groove or recess, substantially as described.

3. In a non-refillable bottle the combination with the neck thereof, provided upon its interior with an annular groove or recess, and an annular flange disposed beneath said recess, of a flexible member seated upon

said flange, a cap seated upon the member and comprising two disks united at their opposite edges, the uppermost of said disks being impermeable and the lower one provided with a valve-opening, a valve controlling said opening and a cap seated upon said cap and provided with an upwardly-convex flange arranged to engage the upper wall of the annular groove or recess and prevent the withdrawal of the parts, substantially as described.

4. In a non-refillable bottle the combination with the neck thereof provided with a cap formed therein, and with an annular groove or recess formed above the cap, of a cap seated upon said cap, and comprising two disks united at their opposite edges by perpendicular braces, the lower of said disks having a valve-opening, a valve controlling said opening, a cap seated on said cap and having an upwardly-convex flange projecting into said groove or recess, one of said braces having a dent formed therein and communicating at its upper end with a vertical groove formed in the neck of the bottle and extending above and below the annular groove or recess, and a vent-tube connected with the lower end of said dent and extending into the lower portion of the bottle, substantially as described.

698,881. CUTTER-HEAD. GEORGE A. SHAW, Milton, Pa. Filed Dec. 4, 1901. Serial No. 94,091. (No model.)

Claim.—1. The combination with the body of a cutter-head comprising a hub bearing a circular flange, of inclined surfaces constituting bit-edges, formed on one side of said flange with their centers in the same plane of revolution, said bit-edges being arranged diametrically opposite each other in pairs and there being two pairs, the opposed pairs having the same degree of inclination with respect to the plane of revolution, the axis of one pair of diametrically-opposed pairs converging and intersecting the axis of the other pair, the axis of the other pair of opposed pairs diverging and intersecting the axis of the first, and bits mounted in said seats, substantially as described.

2. The combination with the body of a cutter-head comprising a hub bearing a circular flange, of inclined surfaces constituting bit-edges with their centers lying in the same plane of revolution, said bit-edges being arranged diametrically opposite each other in pairs and there being two pairs, the axis of one pair of diametrically-opposed pairs converging and intersecting the axis of said cutter-head on one side of said flange, and the axis of the other pair diverging and intersecting the axis of said cutter-head on the other side of said flange, a pair of upright frame-arms seated in one pair of opposed seats and intersecting frame-arms seated in the other pair of opposed seats, said bits being secured by bolts fitting said apertures, substantially as described.

3. The combination with the body of a cutter-head comprising a hub bearing a circular flange, of inclined surfaces constituting bit-edges formed on one side of said flange with their centers in the same plane of revolution, said bit-edges being arranged diametrically opposite each other in pairs and there being two pairs, the axis of one pair of diametrically-opposed pairs converging and intersecting the axis of the cutter-head on one side of said flange, the axis of the other pair of opposed pairs diverging and intersecting the axis of the cutter-head on the other side of said flange, and bits mounted in said seats, substantially as described.

698,882. CENTRIFUGAL SEPARATOR. JEREMIAS H. SHAW, Göttingen, Germany. Filed Dec. 12, 1901. Serial No. 93,931. (No model.)

Claim.—1. In a centrifugal separator, the combination of a drum, its outlet-pipe, a chamber surrounding the ends of the pipes having an internal flange over which the liquid separates in a thin sheet, and a perforated body between the extremities of the outlet-pipe and the projecting edge of the said chamber, substantially as set forth for the purpose set forth.

2. In a centrifugal separator, the combination of a drum, its outlet-pipe, a bowl-shaped ring attached to the drum around the outlet of the pipes, having an inwardly and horizontally projecting flange at a distance from the outlet of said pipes, and a perforated ring inside of the first ring between the outlet-pipe and the flange, substantially as set forth for the purpose set forth.

3. In a centrifugal separator, the combination of a drum, its outlet-pipe, a bowl-shaped ring, attached to the drum around the outlet of the pipes, having an inwardly and horizontally projecting flange above the outlet of said pipes, and a perforated ring inside of the first ring and above the outlet-pipe, substantially as set forth for the purpose set forth.

698,883. HAIR-PARTING. ALFRED G. SMITH, Chicago, Wm. Filed Oct. 20, 1900. Serial No. 93,739. (No model.)

Claim.—A hair-pin comprising a curved tubular head having its ends extending inward toward each other, and said prongs projecting from the ends of the head, the head opening at the head of one of said prongs and closed at the other end, a curved bolt mounted in the head and adapted to project through said opening and extend across the space between the heads of the prongs and to engage a recess in the head of the other prong, the said bolt being adapted to engage a lock of the hair to hold the pin in place, a coil-spring arranged in the closed end of the head and pressing against the inner end of the bolt, to hold it in the locked position, and a thumb-piece connected with the bolt to move the latter against the tension of the spring, the said thumb-piece extending through a slot in the top of the head and being approximately midway between the ends of the head when the bolt is in the locked position.

698,884. SPRING-SCALE. JOHN D. SMITH, Boston, Tex. Filed Aug. 18, 1901. Serial No. 73,181. (No model.)

Claim.—The combination with indicating mechanism, a vertically-movable platform for containing a containing vessel, and operative connection between said platform and said indicating mechanism, of a frame

in which said platform is mounted, the same comprising a pair of longitudinal beams, cross-bars arranged in pairs secured, respectively, to the upper and lower sides of said beams at opposite ends thereof, and springs resting upon the lower of said cross-bars, the said platform being located beneath the upper of said cross-bars, and supported upon said springs, so and for the purpose set forth.

698,985. GYM-FRAME SYNCHRONIC APPARATUS. KARL BERGER, Wiesbaden, Germany. Filed Feb. 16, 1901. Serial No. 47,504. (No model.)

Claim.—1. The combination of a swinging gymnastic apparatus, a stopping device for the same, auto-controlled mechanism for controlling the stopping device and a time device connected with the gymnastic apparatus to be driven therefrom for limiting the period of use.

2. The combination of a gymnastic apparatus, a swinging beam, a motor connected with the beam, a slide arranged to lock the motor, a time device connected with the slide and operated by the movement of the gymnastic apparatus to limit the period of use of the apparatus, and auto-controlled means for releasing the slide.

3. The combination of a swing, a motor arranged to move in time therewith, a sliding lock for said motor, auto-controlled mechanism for throwing the lock into active position, and time-controlled mechanism for holding the lock inactive.

4. The combination of a swing, a lock for restraining the movement thereof, said lock being normally active, auto-controlled mechanism for releasing the lock, and device for holding the lock inactive, said device being periodically actuated from the mechanism of the swing.

5. The combination of a swing, lock device therefor, said device being normally active, and auto-controlled mechanism for releasing said lock device.

6. The combination of a swing, a sliding lock for restraining the movement thereof, said lock being normally active, auto-controlled device for releasing the lock, and mechanism connected with the swing and driven by the movement thereof, said mechanism serving periodically to return the lock to active position.

7. The combination of a swing, a motor attached thereto, a slide serving to lock the motor, a means pressing the slide normally into active position, auto-controlled mechanism for moving the slide into inactive position, a latch holding the slide temporarily in inactive position, and means driven in time with the movement of the swing, whereby periodically to release said latch.

8. The combination of a swing, a locking device therefor, said device being normally active, auto-controlled mechanism for moving the locking device into inactive position, a latch serving to hold the locking device in inactive position, a cam-wheel actuating the latch periodically to release it, and means including a pawl working on the cam-wheel, said means being in connection with the swing to move in time therewith, whereby to actuate the cam-wheel.

698,986. FURNACE. WILLIAM STEUBELER, Bethlehem, Pa. Filed Aug. 22, 1901. Serial No. 78,999. (No model.)

Claim.—1. In a furnace of the character described, air-blast-conducting passages or pipes, and pipes taking gas from the combustion-chamber and adapted to heat the air-blast passing through the first-named passages or pipes, said air-blast, and gas, pipes or passages being arranged in the furnace-walls and delivering into the combustion-chamber, in a plane passing through said chamber, substantially as set forth.

2. In a furnace of the character described, air-pipes comprising upper and lower pipes connecting with an air-supply and connected together by additional pipes, and gas conduits or passages having ports or openings communicating with the combustion-chamber, and surrounding said air-pipes, and said air-pipes and gas-passages delivering at a common point or points, and into said combustion-chamber, all said pipes and passages being arranged in the furnace-walls, substantially as set forth.

3. In a furnace of the character described, air-pipes connecting with an air-supply, comprising upper and lower pipes with intermediate connecting-pipes tubular bodies or sleeves housing said pipes, and gas passages or conduits surrounding said air-pipes and having ports or openings communicating with the combustion-chamber, both said air and gas passages delivering their contents at a common point into said combustion-chamber, all said pipes and passages being arranged in the furnace-walls, substantially as set forth.

4. In a furnace of the character described, a series of air passages or pipes, connecting with an air-supply, two series thereof comprising upper and lower pipes with intermediate pipes tubular bodies or sleeves housing said pipes, a third series of such pipes connecting with the above said two series and having delivering-ports, and having ports or openings communicating with the combustion-chamber, said air-pipes and said gas conduits or passages delivering their contents at a common point or points, into the combustion-chamber, substantially as set forth.

698,987. PROCESS OF MAKING FENCE FABRIC. JOHN H. STICKER, Lawrence, Kans. Filed Nov. 6, 1901. Serial No. 51,999. (No specimens.)

Claim.—1. The herein-described process of making fence fabric, said process consisting in first forming longitudinal warp-wires with diagonal transverse wires in opposite directions, with the loops all on one side of the vertical plane of the wire, and the portions of the wire between the loops ranging alternately in different horizontal planes, then threading straight lengths of transverse wire through said loops and securing the extremities of said transverse wire, and finally carrying a longitudinal pulling tension on said warp-wire, substantially as specified.

698,988. APPARATUS FOR LIFTING WAGON-BODIES. ANTHONY J. TAYLOR, Des Moines, Mont. Filed Feb. 2, 1902. Serial No. 95,399. (No model.)

Claim.—A device for lifting wagons and other articles, comprising a frame open upon one side, wheels mounted under the ends of said frame, and a leg intermediate the closed longitudinal side of the frame, whereby said frame may be held in a horizontal plane, handles projecting from the edge of said closed side, upright posts mounted on the ends of the frame and suitably braced, a winch journaled on said upright posts, a rope or chain secured to and adapted to wind upon said winch and provided with hooks fastened to the end of said rope or chain, a gear-wheel keyed to the end of the winch, a shaft, a worm-wheel rotating with said shaft and in mesh with said gear-wheel, a hand-wheel for rotating said shaft, a collar or washer fastened to said shaft, a cross-piece fastened to one of said uprights and the frame thereon, the upper end of said cross-piece being notched, the under face of said collar or washer adapted to rest flat against the inclined face of said notched portion as shown and described.

698,989. CASE-PARTITION. JAMES C. SHAW, Chicago, Ill. Filed July 14, 1901. Serial No. 61,999. (No model.)

Claim.—The combination with a window-frame, of a window-cash

moving therein, having a hole passing transversely through one of its side bars, the said cash being recessed on its outer edge at the end of said hole, a bolt passing through said hole, having a threaded outer end and a knob upon its inner end, a shoulder on said bolt, a plate surrounding said hole between said shoulder and said knob and secured to the inner surface of the window-cash, a springing clamping-plate fitting the recess in the outer edge of said cash and a yoke pivoted to said clamping-plate, provided with a threaded perforation which is engaged by the outer end of said bolt, substantially as and for the purpose described.

698,940. TOY. HENRY A. VANHORN COOK, Chicago, Ill., assignor to himself and Anthony H. Vanderhoff, Chicago, Ill. Filed Dec. 17, 1901. Serial No. 94,399. (No model.)

Claim.—1. A toy, comprising two receptacles connected together by side plates, rollers arranged in the receptacles, a carrier consisting of an endless band passing around said rollers and having side arranged at intervals, the said band also passing between the side plates, and toy figures having lateral projections by detachably connecting the figures to the carrier, the said projections being curved to prevent interference with the movements of the animals when running, the rollers, substantially as specified.

2. A toy comprising a curve-like receptacle and a receptacle holding a building, side plates connecting the two receptacles, rollers arranged in the receptacles, a carrier consisting of an endless band engaging around the rollers, the said band having side or openings at intervals along its edges, a toy animal or figure, and a base in which the toy animal or figure is supported, the said base having curved lateral projections to engage in said side or openings, whereby interference with the move-

ments of the animal when rounding the rollers is prevented, substantially as specified.

3. A toy, comprising two receptacles connected one with the other, rollers arranged in the receptacles, an endless band engaging around said rollers and having slots or openings arranged at intervals near opposite edges, means for turning one of said rollers, means for preventing lateral movement of the band on the rollers, toy figures, and longitudinally-extending supporting-bases for the figures each having narrow projections at its sides midway between its ends and adapted to removably engage the slots or openings in the band, as specified.

698,841. PROCESS OF TREATING BRINE. GILBERT H. VA, Schweizerbühl, Switzerland. Filed Feb. 18, 1891. Serial No. 62,611. (No specimens.)

Claim.—1. The process of treating brine to obtain crystallized sodium chloride free from gypsum which consists in mixing the brine with slaked lime and ammonium sulfate, passing carbonic acid in the mixture, separating the liquor from the precipitate, evaporating the liquor, separating the crystallized sodium chloride from the mother-lye containing ammonium sulfate and resins, and resins in a subsequent purification to provide the brine with ammonium sulfate, substantially as and for the purpose stated.

2. The process of treating brine to obtain crystallized sodium chloride free from gypsum which consists in mixing the brine with slaked lime, sodium sulfate and ammonium sulfate passing carbonic acid in the mixture, separating the liquor from the precipitate, evaporating the liquor, separating the crystallized sodium chloride from the mother-lye containing ammonium sulfate, and resins, and resins in a subsequent purification to provide the brine with ammonium sulfate substantially as and for the purpose stated.

698,842. BUTTON-SHOWING MACHINE. EDWARD E. WALKER, New York, N. Y., assignor to Alfred Wolf, New York, N. Y. Filed Oct. 18, 1891. Serial No. 73,614. (No model.)

Claim.—1. In a button-showing machine, a needle-bar, means for moving the needle-bar vertically, and means for moving the needle-bar on a horizontal plane to cause a predetermined number of stitches alternately at the inner and outer sides of a button-chuck and then to cause a further horizontal movement to form a buttoning-stitch while the goods remain stationary, substantially as specified.

2. In a button-showing machine, a frame mounted to swing on the machine-arm; a needle-bar carried in the frame, a cam, and a connection between the cam and frame, the cam operating the frame to cause a predetermined number of stitches alternately at the inner and outer sides of a button-chuck, and then to cause a further swinging movement to form a buttoning-stitch, adjustably to the first-named stitches, substantially as specified.

3. A machine for sewing on buttons, comprising a needle-bar, a

swinging frame in which said needle-bar is mounted, means for causing movements of said swinging frame, a bar movable vertically in the swinging frame, a block having pivoted connection with said bar, jaws mounted to swing on said block, a screw-rod for moving said jaws toward and from each other and a spring-yielding pressure-plate operated by said block, substantially as specified.

4. In a machine for sewing on buttons, a needle-bar, means for causing an oscillating movement of the needle-bar, a spring-pressed bar rearward of the needle-bar, a block mounted to swing on said spring-pressed bar, a limiting-arc engaging with the block, jaws mounted on said block to have a vertical swinging movement and to move toward and from each other, and a screw-rod for moving the jaws toward and from each other, substantially as specified.

5. A machine for sewing on buttons, comprising a needle-bar, means for imparting an oscillating motion to said bar, a block arranged rearward of the needle-bar, button-gripping jaws carried by said block, a spring-yielding pressure-plate adapted to be moved downward and held by the block, and an adjustable plate having an opening for the passage of the machine-needle, substantially as specified.

6. A machine for sewing on buttons, comprising a needle-bar, means for imparting an oscillating motion to said needle-bar, a pressure-block rearward of the needle-bar and having a downward and forwardly inclined lower end, a pressure-plate operated by the block, button-gripping jaws mounted on said block so as to swing vertically and toward and from each other, means for adjusting the vertical movement of the jaws, a spring connection between the jaws and the block, and a screw for moving the jaws toward and from each other, substantially as specified.

698,843. GAGE-TIN FOR JOB-PRINTING PRESS. WILLIAM J. WARD, Leominster, Mass., assignor of one-half to Charles C. Eaton, Leominster, Mass. Filed June 6, 1891. Serial No. 68,609. (No model.)

Claim.—1. In a device of the class set forth, the combination of guide-rod for removable application to a plate, a gage-bar adjustably mounted on the said guide-rod, and gage-pins and a side gage adjustably mounted on the said bar, the gage-pins and side gage being pivotally mounted.

2. In a device of the class set forth, the combination of guide-rod for removable application to a plate, a gage-bar having terminal portions freely slidable on the said rods and having clamping-levers pivotally mounted in said terminals to hold the gage-bar in fixed position on the rod, and gage-pins and a side gage adjustably mounted on the said gage-bar and adapted to be moved longitudinally of the latter and also outwardly from and inwardly toward the plate.

3. In a device of the class set forth, the combination of guide-rod for removable application to a plate, a gage-bar adjustably mounted on the said rod, and pivoted gage-pins and a pivoted side gage slidable on the bar and movable outwardly and inwardly toward the same, the pins and side gage having terminal downwardly-bent spurs and horizontal flanges.

4. In a device of the class set forth, the combination of guide-rod for removable application to a plate, a gage-bar adjustably mounted on the said device, and gage-pins and a side gage slidable on the bar and also movable outwardly from and inwardly toward the same.

698,844. PRINTING-FRAME. ALBERT F. WALKER, Bitterroot, Mich., assignor to the Duplex Printing Press Company, Bitterroot, Mich. Filed July 13, 1891. Serial No. 64,993. (No model.)

Claim.—1. The combination of a cylinder and bed, and the bed and cylinder-gearing, one member of each gearing being normally held in place by springs whereby a slight abnormal increase or decrease of speed of movement of the periphery of the cylinder is permitted during impres-

sion by the bodily shifting of one of said members, said spring returning the gearing to proper normal position after impression, substantially as described.

2. The combination of a cylinder and bed, a gear on the cylinder and a rack on the bed or frame meshing with said cylinder-gear, said rack being capable of a slight bodily endwise motion to compensate for slight abnormal increase or decrease of speed of movement of the periphery of the cylinder during impression, and means for returning the rack to normal position thereby compensating for the abnormal movement of the cylinder, substantially as described.

3. The combination of a cylinder and bed, the cylinder-gear, and the two-piece bed-rack meshing continuously therewith; with springs for holding said rack in normal position, but permitting a slight shifting thereof by the cylinder during impressions to compensate for slight overpacking or underpacking of the cylinder and prevent grid or drag on the type, substantially as described.

4. The combination of the cylinder and bed, the cylinder-gear, and a movable bed-rack continuously in mesh with the cylinder-gear and springs at each end of the rack to hold the same in normal position but permit its shifting during impression, substantially as and for the purpose described.

5. The combination of the cylinder, its gear, the bed, and the complete bed-rack having dotted ends and continuously in mesh with the cylinder, guide-pins on the bed or frame engaging the rack-dots, and coil springs interposed between the opposite ends of the rack and legs or steps on the frame for yieldingly holding said rack in position, substantially as described.

698,845. COMPOSITION FOR PREVENTING GROWING PLANTS. JOHN W. WALKER, Windsor, Vt. Filed Nov. 13, 1891. Serial No. 68,608. (No specimens.)

Claim.—1. The herein-described composition of matter, comprising clay one hundred and twenty-eight ounces, common salt one ounce, caustic soda one pint and naphthalene moth-balls, twenty-four.

2. The herein-described composition of matter, comprising ordinary clay, common salt, caustic soda and naphthalene.

698,846. HOOK-BELL. ALBERT E. WOOD, Hartford, Conn. Filed Apr. 13, 1891. Serial No. 64,641. (No model.)

Claim.—1. A reel for storing hose having opposite bands, rings connecting the bands, one of the rings having an intermediate rounded enlargement projected at opposite sides thereof and flush with the outer face of the ring, an unenlarged substantially radial and outwardly-directed hose-engaging projection applied to the outer side of the enlargement and corresponding in cross-sectional size and shape thereto, the length of the projection being greater than the diameter of the hose to be wound upon the reel, and a flange pivoted to the enlargement and entering the hose of the projection, the remaining hose being free from projection,

whereby the hose is prevented from becoming engaged across the inner end of the projection and the entire surface of the reel may be utilized in the winding of hose thereon.

2. The combination with a reel having a substantially horizontal axis, of a support therefor comprising an upright rotatable and outwardly-adjustable member, having at its lower end a laterally-projected yoke-shaped frame straddling the opposite ends of the reel and pivotally supporting the same.

3. A reel rotatable about a horizontal axis, and a frame for supporting the reel, the frame being mounted for rotation about a vertical axis through a complete circle and being vertically adjustable thereby to permit of the reel being raised or lowered as required.

4. A reel comprising two ring-supports each formed with a plurality of arms, rings secured near the extremities of the arms, and a bracket to which the reel is operatively connected, the bracket comprising a yoke connected with the ring-supports, and a reel mounted for rotary movement in suitable brackets.

5. A reel comprising two ring-supports each provided with a plurality of arms and having offset near their extremities, rings connected to the offset, a bracket for supporting the reel, the same comprising a yoke suitably connected with the ring-supports, and a reel mounted for rotary movement in supporting-brackets, the said reel being vertically adjustable in the brackets.

6. A reel comprising two ring-supports each formed with a plurality of reinforced arms and provided near their extremities with offset of greater width than the arms, rings secured to the offset, one of the rings carrying a hose-engaging arm or projection, and a reel-supporting bracket comprising a reel mounted for rotary movement and vertical adjustment in suitable supports, the lower portion of the reel being provided with a yoke to straddle the reel and to be connected with the ring-supports in such manner as to permit the reel to freely rotate on its axis.

698,847. JACQUARD-CARD-PUNCHING MACHINE. GEORGE E. HENRY, Bradford, England. Filed June 14, 1891. Serial No. 64,572. (No model.)

Claim.—1. In a card-punching machine, the combination, with a vertically-slidable frame, and a series of punches carried by the said frame,

of a vertically and horizontally slidable bar, a series of slidable bolts arranged side by side in the said frame and operating to couple the said punches to it when moved over the said punches, and a series of electrically-controlled cores for connecting the said bolts with the said bar, substantially as set forth.

2. In a card-punching machine, the combination, with a vertically-slidable frame, and a series of punches carried by the said frame; of a bar arranged in one side of the said frame, guides constraining the said bar to move horizontally and vertically, a series of slidable bolts arranged side by side in the said frame and operating to couple the said punches to it when moved over the said punches, a series of cores arranged in holes in the said bolts and normally coupling them to the said bar, and electric controlling devices for preventing the said cores from moving vertically with the said bar when required, substantially as set forth.

3. In a card-punching machine, in combination, a punching mechanism consisting of a sliding frame, punches and punch-operating bolts within said frame, a bar having a movement transverse to said sliding frame, solenoids and cores to respectively connect said bolts and bar, means for reciprocating said sliding frame, a receptacle for the cores to be punched, a pusher-plate for carrying forward the movement and therefore, a stepped cam operating said pusher-plate, and means for rotating said stepped cam for progressively moving the card forward to punch the respective rows of holes; and a corresponding electric selecting apparatus for energizing said cores, substantially as described.

4. In a card-punching machine, in combination, a punching mechanism consisting of a sliding frame, punches and punch-operating bolts within said frame, a bar having a movement transverse to said sliding frame, solenoids and two cores for each solenoid, one of said cores serving to respectively connect said bolts and bar; and a corresponding electric selecting apparatus for energizing said cores, substantially as described.

5. In a card-punching machine, in combination, a punching mechanism consisting of a sliding frame, punches and punch-operating bolts within said frame, a bar having a movement transverse to said sliding frame, a ridge provided on said bar, solenoids on said bar and cores within said solenoids, said cores lying in front of said ridge when the respective solenoids are deenergized for connecting the bolts to the bar; and a corresponding electric selecting apparatus for energizing said cores, substantially as described.

6. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a support for the design, which design is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, means for effecting relative progressive movements between said terminals and design corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by the said terminals when lying on the conductive parts of said design, substantially as described.

7. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for the said design which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, means for effecting relative progressive movements between the terminals and the roller carrying the design, said movements corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by the said terminals when lying on the conductive parts of said design, substantially as described.

8. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for the said design, which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, means for effecting relative progressive movements between the terminals and the roller carrying the design, said movements corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by the said terminals when lying on the conductive parts of said design, and means for partially rotating said roller carrying said terminals to lift said terminals from the design before each progressive movement of the sliding frame, substantially as described.

9. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and

cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for the said design which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, means for effecting relative progressive movements between the terminals and the roller carrying the design, said movements corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by the said terminals when lying on the conductive parts of said design, and means for lifting the terminals off the design before each of said progressive movements, substantially as heretofore described.

10. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for said design which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, means for giving to said terminals progressive movements corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by said terminals when lying on the conductive parts of said design, substantially as described.

11. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for said design which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, said terminals being carried within a sliding frame, a stepped cam for giving to said sliding frame progressive movements corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by said terminals when lying on the conductive parts of said design, substantially as described.

12. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for said design which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, said terminals being carried upon a rod mounted within a sliding frame, a stepped cam for giving to said sliding frame progressive movements corresponding to the number of rows of holes to be punched and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by said terminals when lying on the conductive parts of said design, and means for partially rotating said rod carrying said terminals to lift said terminals from the design before each progressive movement of the sliding frame, substantially as described.

13. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for the said design which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, said terminals being carried upon a rod mounted within a sliding frame, a stepped cam for giving to said sliding frame progressive movements corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by said terminals when lying on the conductive parts of said design, and means for partially rotating said rod carrying said terminals to lift said terminals from the design before each progressive movement of the sliding frame, substantially as described.

14. In a card-punching machine, in combination, a punching mechanism, the punches of which are respectively controlled by solenoids and cores, and a corresponding electric selecting apparatus for energizing said cores, consisting of a roller for the said design which is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, said terminals being carried upon a rod mounted within a sliding frame, a stepped cam for giving to said sliding frame progressive movements corresponding to the number of rows of holes to be punched, and electric circuits within which

said terminals and cores are respectively connected, said circuits being completed by said terminals when lying on the conductive parts of said design, and means for partially rotating said rod carrying said terminals to lift said terminals from the design before each progressive movement of the sliding frame, and a lever-and-pawl device for rotating said roller after said progressive movements, said device being operated by means of a bar on the rod carrying said terminals, and a spring to return said sliding frame to its first position, substantially as described.

15. In a card-punching machine, in combination, a punching mechanism consisting of a sliding frame, punches and punch-operating bolts within said frame, a bar carried by said frame, means for giving to said bar a transverse movement on the movement of said sliding frame, solenoids and cores to respectively connect said bolts and bar; and a corresponding electric selecting apparatus for energizing said cores, consisting of a support for the design, which design is marked out into conducting and non-conducting surfaces, a series of terminals normally lying in contact with said design, said terminals being spaced apart a distance equal to the number of rows of holes to be punched, means for effecting relative progressive movements between said terminals and design corresponding to the number of rows of holes to be punched, and electric circuits within which said terminals and cores are respectively connected, said circuits being completed by the said terminals when lying on the conductive parts of said design, substantially as described.

16. In a card-punching machine, in combination, a punching mechanism consisting of a sliding frame, punches and punch-operating bolts in said frame, a bar having a movement transverse to said sliding frame, solenoids and cores to respectively connect said bolts and bar, a main shaft, means connected to said main shaft for reciprocating said sliding frame; and a corresponding electric selecting apparatus for energizing said cores, consisting of a support for the design, said design being marked out into non-conducting and conducting surfaces according to the pattern of the card; terminals in contact with said design, a stepped cam for giving to said terminals progressive movements of a number corresponding to the rows of holes to be punched in the card, and means connected with said main shaft for rotating said cam, substantially as described.

17. In a card-punching machine, in combination, a punching mechanism consisting of a sliding frame, punches and punch-operating bolts in said frame, a bar having a movement transverse to said sliding frame, solenoids and cores to respectively connect said bolts and bar, a main shaft, means connected to said main shaft for reciprocating said sliding frame and for progressively feeding the card under the punches; and a corresponding electric selecting apparatus for energizing said cores, consisting of a support for the design, said design being marked out into non-conducting and conducting surfaces according to the pattern of the card, terminals in contact with said design, a stepped cam for giving to said terminals progressive movements of a number corresponding to the rows of holes to be punched in the card, and means connected with said main shaft for rotating said cam, substantially as described.

698,848. STEAM-EXTRACTOR. GEORGE AUGUSTUS PIERCE, Falmouth, France. Filed Jan. 29, 1902. Serial No. 99,688. (No model.)

Claim.—1. In a boiler having a steam-escape leading to the atmosphere, a superheater, a pipe connecting it with the water in the boiler, a subintegrator, a pipe connecting it with the superheater, a pipe leading from the subintegrator to the atmosphere and to the steam-chamber in the boiler,

and automatic valves in the subintegrator operated by the pressure of the superheated steam, substantially as described.

2. A steam-extractor comprising a boiler, a superheater, a tube having pipes leading from the superheater and to both the boiler and the atmosphere, three pistons in said tube rigidly connected together, one piston exposed to the action of the superheated steam and the others adapted to close or open the pipes to the boiler and atmosphere, respectively, a cylinder, a pipe leading therefrom to the tube, a pipe leading from the cylinder to the tube and branching to meet the pipes leading to the boiler and atmosphere, respectively, and a spring acting upon the pistons in opposition to the superheated pressure, substantially as described.

698,849. FLANTER. JOHN A. ANDERSON, Kansas, U. S. Filed Aug. 27, 1901. Serial No. 73,492. (No model.)

Claim.—1. In a seed-planting attachment, a base-plate having an outlet for seed, a housing for the base-plate, a seed-dropping plate mounted to revolve between the base and housing, said seed-dropping plate having series of seed-carrying openings arranged to successively register with the outlet of the base-plate, and a mechanism for controlling the registry of the seed-dropping openings with the outlet in the base-plate to effect the delivery of seed, substantially as described.

2. In a seed-planting attachment, a base-plate having an outlet for seed, a housing attached to the base-plate, and a seed-dropping plate mounted to turn between the housing and the base-plate, the said seed-dropping plate having series of seed-carrying openings arranged for registry with the seed-outlet together with a series of feed-openings opposite the seed-carrying openings, said seed-carrying plate being also provided with concentric series of regulating-openings, a pin adjustable to any regulating-opening of the series, a spring-controlled support for the pin, a trip for the pin operated by contact with a point on the housing, dogs arranged to enter the feed-openings, and a rotary actuating device for the dogs, substantially as described.

3. In a seed-planting attachment, a base-plate having an outlet for seed, a housing attached to the base-plate, and a seed-dropping plate mounted to turn between the housing and the base-plate, said seed-dropping plate having series of seed-carrying openings arranged for registry with the seed-outlet, together with a series of feed-openings being in two divisions separated by a central partition, the said seed-carrying plate being also provided with a concentric series of regulating-openings outside of the feed-openings, a spring-controlled arm pivotedly attached to the base-plate, which arm is carried up over the periphery of the base and the seed-carrying plate and over the top of the latter, the upper portion of the said spring-controlled arm being provided with a series of apertures, a pin adapted to enter any one of the said apertures and any one of the regulating-openings in the said series, a member attached to the apertured portion of the said arm and extending within the recessed portion of the housing, a shield located at the outer end of the said member, which shield is capable of covering centrally of the feed-openings, a guide-bar pivotedly attached to the member carrying the shield, which guide-bar is passed through a suitable opening in the said pin, a shaft journaled to a support from the base-plate, and dogs differing in length extended from the said shaft, which dogs are adapted to enter the feed-openings in the seed-dropping plate, one at each side of the partition at the forward ends of the said openings, as and for the purpose described.

4. In a seed-planting attachment, a base-plate, a ring-housing for the said base-plate attached thereto, said housing having an extension at its periphery, a seed-dropping plate mounted to revolve between the base-

plate and the housing, the seed-dropping plate being provided with a circularly-arranged series of seed-receiving openings, a cap on the extension of the ring-housing, and a hinged wiper arranged beneath the cap, said wiper having its blade extending downwardly and diagonally of the seed-dropping plate and in the path of the seed-receiving openings as the said seed-dropping plate is revolved, substantially as described.

5. In a seed-planting attachment, a base-plate, a ring-housing for the said base-plate attached thereto, said housing having effects at its periphery, a seed-dropping plate mounted to revolve between its base-plate and the housing, the seed-dropping plate being provided with a circularly-arranged series of seed-receiving openings, a cap on each of the extensions of the ring-housing, pivoted wipers carried by the said caps, the blades of the wipers being arranged diagonally of the seed-dropping plate and in the path of the seed-receiving openings as the said seed-dropping plate is revolved, chambers formed at the under portion of the said ring-housing, and spring-controlled detents within the said chambers, which detents are arranged to enter the seed-dropping openings as the seed-dropping plate revolves, the wipers serving to remove excess of seed from the seed-carrying openings and the detents serving to prevent the seed-dropping plate from turning in a reverse direction, as set forth.

6. In a seed planter the combination with a base-plate having a seed-opening, a ring-housing attached to the base-plate and having extensions at its periphery, and a chamber in its upper face, and a seed-dropping plate having a plurality of seed-openings and arranged between the base-plate and housing, of a cap on each of the extensions of the housing, pivoted wipers carried by the housings beneath the caps and having their blades extending downwardly and diagonally of the seed-plate, and a pivoted and spring-pressed discharge-arm in the chamber of the housing, as set forth.

7. In a seed-planter, the combination with a seed-plate having a plurality of seed-openings, each adapted to receive a single seed, and means for operating said seed-plate, of mechanism for controlling the operation of the seed-plate-opening means to temporarily stop the said seed-plate to permit more or less seed to be delivered to a hill, as set forth.

8. In a seed-planter, the combination with revolvable seed-plate having a plurality of seed-openings, each adapted to receive a single seed, and means for engaging the seed-plate to revolve the same, of a device adapted to be moved between the seed-plate and one of the pivots to prevent the pivot from operating the seed-plate, as set forth.

9. In a seed-planter, the combination with a revolvable seed-plate having a plurality of seed-openings, each adapted to receive a single grain, and an opening at the side of each seed-opening, and pivots for engaging the said openings to revolve the plate, the said pivots engaging a different opening of a plate fitted to slide on the seed-plate over the openings at the side of the seed-openings, and means for controlling the movement of said plate, as set forth.

698,850. ACCOUNT-FILE. WILLIAM E. ANDERSON, Fulton, Mo.
Filed June 6, 1901. Serial No. 69,001. (No model.)

Claim.—1. A file-box open at one side, and having its interior entirely unobstructed, and composed of the two twin hinged sections, having laterally-located corner posts or abutments adapted to completely fill or engage later-extension notches of index-cards, and registering when the box is closed, substantially as specified.

2. The combination with the index-cards, each of which has a corner-notch at the forward or index side thereof, each notches being of the same dimension, and being bounded on one side by the outer edge of the card proper, and on the other side by the latter extension, of the file-box, each box being open at one side, and consisting of the two twin sections having laterally-located corner posts or abutments at each open side, and of a thickness or inner extent equal to the width of the latter extension of the index-card, said posts registering when the box is closed, substantially as specified.

698,851. ROLLER-BEARING. LEONARD F. ANDERSON, Providence, R. I., assignor to Standard & Granite Manufacturing Company, Providence, R. I. Filed Mar. 23, 1901. Serial No. 61,990. (No model.)

Claim.—1. A roller-bearing comprising a cage having an inner outer periphery and an open center with a plurality of radiating slots opening into said center, rollers fitting in said slots, and means for confining the rollers in the slots, substantially as described.

2. A roller-bearing comprising a cage having radiating slots formed therein, rollers within said slots, said cage having independent plates overlapping the edges of the slots to retain the same in place, substantially as described.

3. A roller-bearing comprising a cage of circular disk form having an open center and inner outer periphery and having radiating slots opening into said center, rollers retained in said slots, and horizontal bearing-plates inserted transversely through the plate at the outer ends of said slots, substantially as described.

698,852. ROLLING-PLATE. JAMES J. ANDERSON, Houston, Tex.
Filed Aug. 4, 1900. Serial No. 26,000. (No model.)

Claim.—1. In a press of the character described, the combination with the follower and a compressing-head arranged directly over said follower, of a circular series of conical rollers supported by said head, means for causing a relative rotation between said follower and said compressing-head, and means actuated by the rotatable element for imparting an independent positive rotation to the individual conical rollers at slightly more than normal speed, substantially as set forth.

2. In a press of the character described, the combination with the follower, of a series of compressing-rollers arranged over said follower, and driving means for imparting an independent positive rotation to said rollers at slightly more than normal speed, substantially as set forth.

3. In a press of the character described, the combination with the follower, of a series of compressing-rollers cooperating with said follower, and means for imparting a positive rotation to said rollers at slightly more than normal speed, substantially as set forth.

4. In a press of the character described, the combination with the rolling-chamber, of a series of conical compressing-rollers cooperating with said chamber, and means for causing an independent positive rotation of said rollers at slightly more than normal speed.

5. In a press of the character described, the combination with the rolling-chamber, of a series of compressing-rollers arranged over said chamber, driving means for imparting an independent positive rotation to said rollers, and separate means for varying the peripheral speed of said rollers, substantially as set forth.

6. In a press of the character described, the combination with the rolling-chamber, of a circular series of conical pressing-rollers cooperating with the chamber, means for imparting a positive rotation to said rollers, and means for causing a variation of the peripheral speed of said rollers within the plane of the rolling-chamber, substantially as set forth.

7. In a press of the character described, the combination with the rolling-chamber, of a roller-carriage, a series of conical rollers supported by said carriage, means for maintaining a relative rotation between the chamber and said carriage, means for imparting an independent positive rotation to the individual rollers, and separate means for causing a variation in the peripheral speed of the rollers within the plane of the rolling-chamber, substantially as set forth.

8. In a press of the character described, the combination of the rolling-

chamber, a series of pressing-rollers, cooperating with said chamber, and means for varying the peripheral speed of said rollers, substantially as set forth.

9. In a press of the character described, the combination of the rolling-chamber, a series of conical pressing-rollers cooperating with said chamber, and means for causing a variation in the peripheral speed of the conical rollers within the plane of the rolling-chamber, substantially as set forth.

10. In a press of the character described, the combination of the rolling-chamber, a horizontal circular series of conical pressing-rollers grouped at the head of the rolling-chamber, and having a projection outside of the plane thereof, and means for varying the extent of the peripheral surface of the rollers within the plane of the rolling-chamber to provide for varying the peripheral speed thereof, substantially as set forth.

11. In a press of the character described, a fixed rolling-chamber, a revolvable roller-carriage arranged at the head of said chamber, a series of conical pressing-rollers carried by said carriage, means for imparting a rotary movement to the carriage, and means actuated by the movement of the revolvable carriage for imparting an independent positive rotation to the individual rollers at slightly more than normal speed, to cause them to compress the crutch formed in advance of the rollers by the compression of the cotton, substantially as set forth.

12. In a press of the character described, the combination of a rolling-chamber, a roller-carriage arranged at the head of the chamber, a series of conical pressing-rollers supported by the carriage and capable of longitudinal movement, adjustable bearing-supports for said rollers to provide for varying the projection thereof within the vertical plane of the rolling-chamber, and means for causing a relative rotation between the rolling-chamber and the carriage, substantially as set forth.

13. In a press of the character described, a fixed rolling-chamber, a revolvable roller-carriage arranged at the head of the chamber, a circular series of conical pressing-rollers grouped within the carriage, adjustable bearing-supports for the rollers to provide for the longitudinal adjustment thereof to vary their projection within the vertical plane of the rolling-chamber, means for rotating the carriage, and separate means for independently rotating the rollers, substantially as set forth.

14. In a press of the character described, the combination of a fixed supporting-frame having a stationary circular rack, a rolling-chamber pivoted from the supporting-frame, a revolvable roller-carriage, and a series of conical rollers supported by the carriage and carrying individual driving-gears meshing with said rack and caused to roll thereon by the movement of the carriage, but at slightly more than normal speed, substantially as set forth.

15. In a press of the character described, the combination of a supporting-frame having a stationary circular rack, a revolvable roller-carriage having an interior pendant bearing-hanger, a series of conical pressing-rollers supported by the carriage and movable therewith, said rollers being provided with inner and outer spindle extremities having bearing-supports, and driving-gears mounted on the outer spindle extremities of the rollers and having hub portions journaled in said pendant bearing-hanger, said driving-gears meshing with the circular rack of the supporting-frame and caused to roll thereon by the movement of the carriage, but at slightly more than normal speed, substantially as set forth.

16. In a press of the character described, the combination of the supporting-frame having a circular rack, a rolling-chamber pivoted from said frame, a revolvable roller-carriage, mounted within the frame, and provided with a central bearing-hub and an outer pendant rim, a series of conical pressing-rollers grouped within the open center of the carriage and having a projection outside of the plane of the rolling-chamber, said rollers having inner and outer spindle extremities, the inner of which have a loose bearing in the central bearing-hub, adjustable bearing-covers mounted in the outer rim of the carriage, and engaging with the outer spindle extremities of the rollers, driving-gears for the individual rollers loosely keyed or splined upon the outer spindle extremities thereof and supported within the carriage, and separate means for rotating the carriage, substantially as set forth.

17. In a press of the character described, the combination with the pressing mechanism and the follower having wire-receiving grooves in the face thereof, of a rolling cylinder or chamber provided with a plurality of longitudinally-disposed de-rotating slots cooperating with the grooves of the follower, removable filling-strips fitting in the slots of the rolling cylinder or chamber, and fastening means for said filling-strips, substantially as set forth.

18. In a press of the character described, the combination with the rolling-chamber, of a compressing-head arranged over said chamber, a circular series of conical rollers supported by said head, means for causing a relative rotation between the rolling-chamber and head, means actuated by the rotatable press member for rotating the rollers at slightly more than normal speed, and means for changing the speed of the rollers.

19. In a press of the character described, the combination with a

follower and a compressing-head in opposed relation, of a circular series of conical rollers supported by the head, means for effecting the relative rotation of the follower and compressing-head, and means for rotating the individual rollers at slightly more than the normal speed, whereby the tendency of the fiber to break up in advance of the rollers is overcome.

698,853. ROLLING-PLATE. JAMES J. ANDERSON, Houston, Tex.
Filed Apr. 17, 1901. Serial No. 64,990. (No model.)

Claim.—1. In a press of the character described, the combination with a rolling-chamber and a compressing-head, of means for effecting the relative rotation of the head and chamber, and means for opposing resistance to the undue drawing of the fiber, of the bale loaded within the chamber, toward the center of the bale from the outer portion thereof.

2. In a press of the character described, the combination with a rolling-chamber and a compressing-head, of means for effecting the relative rotation of the head and chamber, and a compression member carried by the head and bearing against the face of the bale at or adjacent to the outer edge only thereof to prevent the undue drawing of the fiber toward the center of the bale.

3. In a press of the character described, the combination with a follower and a compressing-head including a series of compressing members, of a compression device disposed intermediate of the compressing members and bearing against the face of the bale to prevent undue drawing of the fiber toward the center thereof.

4. In a press of the character described, the combination with a rolling-chamber, of a compressing-head arranged over said chamber, a circular series of conical rollers supported by said head and disposed within the plane of the rolling-chamber, means for causing a relative rotation between the rolling-chamber and said compressing-head, and means disposed intermediate of the rollers for opposing resistance to the undue drawing of the fiber toward the center of the bale.

5. In a press of the character described, the combination with a rolling-chamber, of a compressing-head arranged over said chamber, a circular series of conical rollers supported by said head, means for causing a relative rotation between the rolling-chamber and said compressing-head, and a compression-ring disposed to bear against the end of the bale at points intermediate of the rollers to oppose a resistance to the undue drawing of the fiber toward the center of the bale.

6. In a press of the character described, the combination with a rolling-chamber, of a compressing-head arranged over said chamber, and provided with a compression-ring located above, but within the circumferential plane of, said chamber, a circular series of conical rollers supported by said head and disposed in the vertical plane of the rolling-chamber, the under sides of said rollers being disposed in a plane slightly below the plane of the lower edge of the compression-ring, and means for causing a relative rotation between the rolling-chamber and said compressing-head, whereby the bale will be compressed and undue drawing of the fiber toward the center of the bale will be prevented by the compression-ring.

7. In a press of the character described, the combination with a rolling-chamber, of a compressing-head arranged over said chamber and provided with a compression-ring, concentric with but of smaller diameter than the chamber and divided to form a feed-opening, a guard for said feed-opening disposed substantially in the vertical plane of the wall of the rolling-chamber, and a series of conical rollers supported by said head and passed through the compression-ring.

8. In a press of the character described, the combination with a rolling-chamber, of a compressing-head arranged over said chamber, and having a pendant inner wall constituting a compression-ring concentric with but of smaller diameter than the rolling-chamber, and a series of compressing rollers supported by the head and passed through the compression-ring.

9. In a press of the character described, the combination with a rolling-chamber, of a compressing-head arranged over said chamber and provided with a pendant inner wall constituting a compression-ring concentric with but of smaller diameter than the rolling-chamber, said wall being divided to form a feed-opening, one side of which is inclined, a guard

plate disposed directly opposite the feed-opening, and a circular series of conical rollers supported by the head and passed through the guard-ring, said rollers being disposed to define a feed-space in line with the opening in the ring.

10. In a press of the character described, the combination with a balling-chamber, of a compressing-head arranged over said chamber and having a pendant inner wall concentric with but of smaller diameter than the chamber, and divided at one side to form a feed-opening, a spring-ring encircling the upper end of the compressing-head, a guard-ring encircling the spring-ring and retained within the head, said guard-ring being provided with a pendant guard-plate arranged opposite the opening in the ring, a series of conical rollers supported by the head, and means for effecting the relative rotation of the head and chamber.

11. In a press of the character described, the combination with a balling-chamber, of a compressing-head arranged over said chamber, a circular series of conical rollers supported by said head and disposed within the plane of the balling-chamber, means for causing a relative rotation between the balling-chamber and the compressing-head, means for positively actuating the rollers, and means disposed intermediate of the rollers for resisting the undue drawing of the fiber toward the center of the bale from the outer portion thereof.

12. In a press of the character described, the combination with a balling-chamber, of a compressing-head provided with a series of conical rollers supported by said head and having mutually-journalled inner and outer spindles, adjustment-curved disposed to shift said rollers longitudinally, and antifriction-balls interposed between the spindles and the adjacent ends of the roller-spindles.

13. In a press of the character described, the combination with a follower, of a compressing-head arranged over said follower, a circular series of conical rollers supported by said head, means for causing a relative rotation between said follower and said compressing-head, and a compressing-ring disposed to bear against the end of the bale at points intermediate of the rollers to oppose a resistance to the undue drawing of the fiber toward the center of the bale.

14. In a press of the character described, the combination with a follower, of a compressing-head arranged over said follower and provided with a compression-ring concentric with but of smaller diameter than the follower and divided to form a feed-opening, and a series of conical rollers supported by said head and passed through the compression-ring.

15. In a press of the character described, the combination with a follower, of a compressing-head arranged over said follower and having a pendant inner wall constituting a compression-ring concentric with but of smaller diameter than the follower, and a series of compressing-rollers supported by the head and passed through the compression-ring.

16. In a press of the character described, the combination with a follower, of a compressing-head arranged over said follower, and composed of a series of conical rollers, said head having a pendant inner wall constituting a compression-ring concentric with but of smaller diameter than the follower, and means for imparting an independent positive rotation to said rollers at slightly more than normal speed.

17. In a press of the character described, the combination with a balling-chamber, and a compressing-head, of means for effecting the relative rotation of the head and chamber, and means located within the chamber for opposing resistance to the undue drawing of the fiber toward the center of the bale from the outer portion thereof.

698,854. METHOD OF BURNING OIL. GEORGE I. BARNES, Quincy, Mass., assignor to Republic Auto-Fuel, Power and Burner Company, Portland, Me., and Lynn, Mass., a Corporation of Maine. Filed Aug. 2, 1900. Serial No. 26,712. (No specimens.)

Claim.—1. The method of converting hydrocarbons for fuel, which consists of vaporizing the hydrocarbons or oil under pressure by heat, dividing the supply of vapor into two jets, mixing each jet of vapor with air, additionally mixing, by the expansive force of the oil-vapor, with each jet of mixed vapor and air, a further supply of air proportional to the amount of vapor supplied by each jet, commingling the several jets of mixed vapor and air, and igniting the mixture, substantially as set forth.

2. The described process of converting hydrocarbons for fuel, which consists of vaporizing the hydrocarbons or oil under pressure by heat, dividing the supply of vapor into two jets, mixing each jet of vapor with air, additionally mixing, by the expansive force of the oil-vapor, a further supply of air therewith, feeding said additional air-supply successively in separate quantities to the oil-vapor within the mixing-passages, commingling the several jets of mixed vapor and air, and igniting the mixture, substantially as set forth.

3. The method of converting hydrocarbons for fuel, which consists of vaporizing the hydrocarbons or oil under pressure by heat, dividing the supply of vapor into two jets, mixing each jet of vapor with air, additionally mixing, by the expansive force of the oil-vapor, with each mixed vapor

and air jet, an additional air-supply, feeding progressively each additional air-supply with the increased volume of the vapor-jet, proportional to the amount of vapor supplied by each jet, commingling the several mixed vapor and air jets, and igniting the mixture, substantially as set forth.

698,855. PROCESS OF MAKING AROMATIC ALDEHYDES AND ACIDS. MAX RAUEN, Ludwigshafen, Germany, assignor to Badische Anilin- & Soda-Fabrik, Ludwigshafen, Germany, a Corporation of Baden, Germany. Filed Mar. 16, 1901. Serial No. 51,097. (No specimens.)

Claim.—1. The process of making aromatic aldehyde and acid which consists in treating a benzoinolone-defined telonic substance with the peracid of a metal of the nickel group, a salt of a metal of the nickel group and a suitable oxidizing agent.

2. The process of making aromatic aldehyde and acid which consists in treating a benzoinolone-defined telonic substance with the peracid of a metal of the nickel group and a salt of a metal of the nickel group.

3. The process of making aromatic aldehyde and acid which consists in treating a benzoinolone-defined telonic substance with the peracid of a metal of the nickel group.

4. The process of making ortho-nitro-benzaldehyde and ortho-nitro-benzoic acid which consists in treating ortho-nitro-telonic with nickel peracid, nickel chloride and sodium hypochlorite.

698,856. INDICATOR. BENJ. V. BARNES, Boston, Mass. Filed Apr. 15, 1901. Serial No. 54,900. (No model.)

Claim.—1. An indicator, correcting means having a predetermined influence in opposite directions to correct said indicator to its fractional divisions, said means being operative throughout the cycle of the indicator, a unidirectional influence-propelling shaft, and a clip connection between said indicator and shaft.

2. A primary indicator, a secondary indicator actuated proportionately thereto, provision for ranging the primary indicator independently of the secondary indicator, and means actuated by the rotating of the primary indicator and having a predetermined influence in opposite directions to correct said secondary indicator to its fractional divisions.

3. A primary indicator having a series of indicating divisions on or between which it indicates, a secondary indicator actuated proportionately to said primary indicator, provision for ranging the primary indicator independently of the secondary indicator, and means actuated by the rotating of the primary indicator for correcting the secondary indicator to the amount of said divisions indicated by the primary indicator.

4. An indicator, and a correcting device therefor comprising a rotary member connected to the indicator and a stationary member, one of which is a wheel having a series of cam divisions and the other a coasting cam-dog adapted to register the cam divisions with itself, and provision for bringing said members into and out of coasting relation.

5. A device for indicating the measurements of a series of articles comprising a shaft whose rotary movements are to be measured, a total indicator provided with a movable indicating member having a clip connection with said shaft, a primary indicator for individual indications provided with a movable indicating member having a clip connection with said shaft whereby it may be returned after an indication, and a correcting device for the total indicator comprising a rotary member connected to the movable total-indicator member, and a stationary member, one of which is a wheel having a series of cam divisions and the other a coasting cam-dog adapted to register the cam divisions with itself, and provision for bringing said members of the correcting device into coasting relation by the return of said movable primary-indicator member.

6. In an indicating device, a unidirectional shaft, an indicating member adapted to measure the rotation of said shaft and having a clip connection therewith permitting it to be reset with respect thereto, and a counter operated by said indicating member and adapted to count the strokes thereof.

698,857. FIFTH-AND-GREENS. GEORGE W. BARN, Boston, Mass., assignor of one-half to John A. Parker, Boston, Mass. Filed Nov. 15, 1901. Serial No. 52,425. (No model.)

Claim.—1. The combination with a piston-rod connection of the character specified, of locking means therefor, comprising laterally-movable members associated with the rod-end members, and means for forcing the movable members to bring the rod-end members into engagement with the ball.

2. The combination with a ball-and-socket piston-rod connection of locking means therefor comprising laterally-movable spring-pressed members associated with the rod-end members, means for returning the movable members to bring the rod-end members into engagement with the ball, and mechanism for locking the said means in adjusted position.

3. The combination with a ball-and-socket piston-rod connection, of locking means therefor comprising two laterally-movable plates carried by the rod-end members, and provided intermediate of their ends with openings, a pivoted dog having a part to engage the openings to effect lateral rotation of the plates, and means for locking the dog in its adjusted position.

4. The combination with a ball-and-socket piston-rod connection, of locking means therefor comprising two laterally-movable plates, each provided with an opening intermediate of its ends, and with means for limiting its range of lateral movement, springs carried by the outer portions of the plates and operating normally to hold the rod-end members separated, a dog provided with a toe for engaging said openings to retract the plates laterally to bring the rod-end members into engagement with the ball, and a collar mounted on the rod-end member and having a detent to engage teeth or cam-faces on the dog, whereby to hold the same in its adjusted position.

5. The combination with a ball-and-socket piston-rod connection, of locking means therefor, comprising two laterally-movable plates each provided intermediate of its ends with an opening and with means for limiting its range of lateral movement, a pivoted dog having a part to engage the openings to effect lateral rotation of the plates, and means for locking the dog in its adjusted position.

698,858. MAIL-BAG DELIVERER AND CATCHER. GEORGE R. BARNES, Princeton Junction, N. J. Filed Nov. 2, 1901. Serial No. 51,098. (No model.)

Claim.—1. In a device of the class described, the combination with a crane having means for suspending a mail-bag at a station, of an arm hinged to swing toward and from the crane and provided with devices for engaging with said bag-suspension means, a car-bag catcher mounted and projecting from one side of the swing-arm and provided with a holding member and with a catch arranged to cooperate with said member.

2. In a device of the class described, the combination with a station-crane having bag-suspension devices, of an arm hinged to swing toward and from the crane, and having means adapted to engage with said station-crane devices, and a car-bag catcher yieldably mounted on said swing-arm and capable of a combined movement relative thereto under the impact of a car-bag, said catcher being movable with the swing-arm and having a holding member, and a catch arranged to cooperate with said member.

3. In a device of the class described, the combination with a station-crane, of a two-part swing-arm, one of the members of said arm being pivoted on the crane, and the other member being slidably fitted to the pivoted member, said slidable member being normally impelled by a spring, and having means adapted for engagement with a station-crane device.

4. A mail-bag deliverer and catcher, comprising an arm on the mail-car, a catcher yieldably mounted on the car-arm, a station mail-pouch support adapted to be engaged by said catcher on the car-arm and to be removed thereby from the station, a spring station-arm held in an active position by said station mail-pouch support, a catcher yieldably held on said station-arm, and a car mail-pouch support carried by the car-arm and adapted to be delivered by the crane to the second-named catcher which is carried by the spring station-arm.

8. A device of the class described, provided with a mail-pouch support comprising a ring, an eye on the ring, arms pivoted on the eye, and a locking device for locking the free ends of the arms together, as set forth.

9. A device of the class described, provided with a mail-pouch support comprising a ring, an eye on the ring, arms pivoted on the eye, and a locking device for locking the free ends of the arms together, the said locking device consisting of a shank on the free end of one of the arms and having an arrow-head, and spring-pressed catches on the free end of the other arm and adapted to engage the said arrow-head, as set forth.

10. A device of the class described, provided with a station-post, a lever fulcrumed thereon, a ring removably hung on the said lever, a mail-pouch holder suspended on the said ring, an arm fulcrumed on the post, a spring-pressed slide movable in the said arm, and a pin on the said slide for engaging the said ring to hold the arm and slide in an operative position, as set forth.

11. A device of the class described, provided with a station-post, a lever fulcrumed thereon, a ring removably hung on the said lever, a mail-pouch holder suspended on the said ring, an arm fulcrumed on the post, a spring-pressed slide movable in the said arm, a pin on the said slide for engaging the said ring to hold the arm and slide in an operative position, and a catch held in the said slide to receive the ear mail-pouch carrier, as set forth.

12. A device of the class described, provided with a station-post, a lever fulcrumed thereon, a ring removably hung on the said lever, a mail-pouch holder suspended on the said ring, an arm fulcrumed on the post, a spring-pressed slide movable in the said arm, a pin on the said slide for engaging the said ring to hold the arm and slide in an operative position, and a catch held in the said slide to receive the ear mail-pouch carrier, the said catch comprising a shank mounted to slide on the pin and having a nose, and a spring-pressed catch operating in conjunction with the said nose, as set forth.

13. A device of the class described, provided with a station-post, a lever fulcrumed thereon, a ring removably hung on the said lever, a mail-pouch holder suspended on the said ring, an arm fulcrumed on the post, a spring-pressed slide movable in the said arm, a pin on the said slide for engaging the said ring to hold the arm and slide in an operative position, and a catch held in the said slide to receive the ear mail-pouch carrier, the said catch comprising a shank mounted to slide on the pin and having a nose, a spring-pressed catch operating in conjunction with the said nose, and a cross-bar on the said shank, and carrying a second shank on which the spring-pressed catch is fulcrumed, as set forth.

14. A device of the class described, provided with a station-post, a lever fulcrumed thereon, a ring removably hung on the said lever, a mail-pouch holder suspended on the said ring, an arm fulcrumed on the post, a spring-pressed slide movable in the said arm, a pin on the said slide for engaging the said ring to hold the arm and slide in an operative position, a catch held in the said slide to receive the ear mail-pouch carrier, the said catch comprising a shank mounted to slide on the pin and having a nose, a spring-pressed catch operating in conjunction with the said nose, and a cross-bar on the said shank, and carrying a second shank on which the spring-pressed catch is fulcrumed, as set forth.

15. A device of the class described, provided with a station-post, a lever fulcrumed thereon, a ring removably hung on the said lever, a mail-pouch holder suspended on the said ring, an arm fulcrumed on the post, a spring-pressed slide movable in the said arm, a pin on the said slide for engaging the said ring to hold the arm and slide in an operative position, a catch held in the said slide to receive the ear mail-pouch carrier, the said catch comprising a shank mounted to slide on the pin and having a nose, a spring-pressed catch operating in conjunction with the said nose, and a cross-bar on the said shank, and carrying a second shank on which the spring-pressed catch is fulcrumed, and a spring interposed between the cross-bar and slide, as set forth.

16. In a device of the class described, the combination with a movable ear-arm, of a guide-arm projecting therefrom, and a station-bag catcher yieldably mounted on said guide-arm to give backwardly to the impact of a station mail-bag, said catcher having a holder member and a catch cooperating therewith.

17. A device of the class described, having a car-arm, a supporting-arm rigid thereon, a catch on the supporting-arm, a pivoted arm on the said car-arm, and a catch on the pivoted arm, as set forth.

18. In a device of the class described, the combination with a car-arm, of a guide-arm projecting therefrom, a station-bag catcher yieldably mounted on said guide-arm, and means operatively related to said catcher to absorb the shock due to the impact of a bag with the catcher.

19. In a device of the class described, a bag-catcher comprising a hollow holding member provided with a nose at its extremity, a cross-bar held with said member and provided with a shank that lies adjacent to the member, and a yieldable catch mounted on the shank and opening the space between the shank and the member to cooperate with the nose thereof.

20. In a device of the class described, a bag-catcher having a holding member provided with a laterally-extending nose, a shank adjacent

to said member, and a yieldable catch opening the space between the member and the shank, said catch being mounted on said shank to open inwardly from the nose and adapted to be seated firmly against said nose and to be limited in its closing movement thereby.

21. In a device of the class described, the combination with a station-arm, and a swing-arm thereon, of a pin carried by said arm, a car-bag catcher yieldably mounted on an end portion of said pin and provided with a holding member and a catch, means for limiting the movement of the catcher, and a cushion device opposing the movement of the catcher.

698,859. SPLIT-PULLEY RANGER. JAMES W. BERRY, Tacoma, Wash., assignor to Tacoma Automatic Scales Co., Tacoma, Wash. Filed Aug. 31, 1901. Serial No. 73,908. (No model.)

Claim.—1. The combination with a split pulley of a swinging arm or hook pivotally attached to one side of one half of a split pulley, said arm or hook so formed as to swing over and engage the pulley-shaft and support the half of the split pulley thereon.

2. The combination with a split pulley of a pair of arms or hooks pivotally attached, one on each side of one part of said pulley, said arms so formed as to swing over and engage the pulley-shaft and support the one part of the split pulley thereon while the other part is being held thereby and in place.

698,860. ROTARY ENGINE. ROBERT B. BENT, Bagby, Minn. Filed Jan. 4, 1902. Serial No. 351. (No model.)

Claim.—1. A rotary engine having a cylinder, a piston working therein, a slide-valve controlling the supply of steam to the cylinder, an eccentric driven from the piston, a rock-shaft driven from the eccentric, and a notched arm connected with the valve and adapted adjustably to engage a part of the rock-shaft to be actuated therefrom.

2. A rotary engine, having a cylinder, a piston working therein, a piston-rod mounted in the piston, and working through an opening therein, means connected with the piston-rod to cause the movement thereof, and a hollow roller against which the piston-rod bears, the roller having perforations permitting a lubricant to be expelled from the interior of the roller.

3. A rotary engine having a cylinder divided into a plurality of concentrically-disposed compartments, a piston working in each compartment of the cylinder, the pistons being connected together, a piston-rod for each piston, the piston-rods sliding radially in the pistons, a movement-transmitting means located outside of the engine and connected with the pistons, a stationary crank-shaft passed through the piston-rods, means connecting the piston-rods with said crank-shaft, and valve devices for con-

rolling the passage of steam from one compartment of the cylinder to the other, the cylinder being formed with a passage leading between the compartments, for the purpose specified.

4. The combination of a cylinder, a piston arranged concentrically therein, a piston-rod sliding radially in the piston, a stationary crank-shaft disposed centrally of the piston, an arm journaled on the crank of said shaft, the arm extending to the working end of the piston-rod and having a transverse enlargement mounted to rest in said outer end of the piston-rod, the enlargement of the arm bearing against the interior wall of the cylinder, and a positive connection between the outer end of the piston-rod and the said enlargement and arranged to permit of the rocking movement of the latter, the piston being mounted to turn on the stationary shaft, thereby causing the arm journaled on the crank to move the piston-head, for the purpose specified.

698,861. OIL-BURNER FOR FURNACES. WILLIAM BROWN, San Francisco, Cal. Filed Oct. 14, 1901. Serial No. 73,681. (No model.)

Claim.—1. An oil-burner of the class described for spraying crude oil into furnaces, consisting of a flat rectangular casing provided with an oil-passage and adjacent steam-passage, separated by a partition; a nipple bolted onto the casing in front of the partition, the interior of said nipple forming a chamber, a horizontal floor in said chamber and a slit in the forward end of the nipple in line with the floor of the chamber, substantially as described.

2. In an oil-burner of the class described for spraying crude oil into furnaces, a flat rectangular nipple secured to the front end of the burner; a rectangular chamber in said nipple, a horizontal slit entirely across the front and extending for a distance back along each side of the extremity of the nipple which projects into the furnace, substantially as described.

3. In an oil-burner for intermingling steam and oil and spraying them into a furnace, a rectangular chamber in the forward end of the burner or nozzle in front of the partition which separates the oil and steam passages, a horizontal floor in said chamber and a slotted opening in the front end of the nozzle in line with the floor of the chamber, substantially as described.

698,862. MEANS FOR COMPRESSION OF LIQUEFIED GASES. ROBERT BENTLEY, Cambridge, Mass. Filed June 7, 1902. Serial No. 14,881. (No model.)

Claim.—1. Means for compressing and liquefying gas, which consists in a compressing-cylinder open at its bottom, a gas-receiver carried by the upper portion of the cylinder, a communication between the gas-receiver and cylinder, which communication is normally closed by a valve opening inwardly in the receiver, the said receiver being provided with a substantially horizontal chamber between its inner and outer walls in communication with the main chamber, and means for drawing off the compressed gas from the receiver, as set forth.

2. Means for compressing and liquefying gas, which consists in a compressing-cylinder open at its bottom, a gas-receiver carried by the upper portion of the cylinder, a communication between the gas-receiver and cylinder, which communication is normally closed by a valve opening inwardly in the receiver, the said receiver being provided with a substantially horizontal chamber between its inner and outer walls in communication with the main chamber, and means for drawing off the compressed gas from the receiver, as set forth.

with the main chamber, means for drawing off the compressed air from the receiver, projections from the cylinder, weights suspended from the said projections, and means for manually displacing the weights from the cylinder, the said weights being adapted also to automatically disconnect themselves from the cylinder when the air in the cylinder has been compressed in the receiver, as set forth.

3. A deep-on apparatus for the liquefaction of gases, comprising an open receptacle and two closed receptacles, said open receptacle communicating with one of said closed receptacles by means of a valve, and said closed receptacles communicating with each other by means of another valve, and means for sliding said receptacles into the deep on and raising the same therefrom.

4. A deep-on apparatus for the liquefaction of gases, comprising an open receptacle and a receptacle closed by a valve, said receptacles communicating with each other, detachable weights for sliding said receptacles into the on, and means for disengaging said detachable weights at will.

698,868. SAW-PROTECTING DEVICE. AUGUSTE BURMEISTER, Valreux, France. Filed Aug. 7, 1901. Serial No. 71,582. (No model.)

Claim.—1. The combination of a saw-blade, a saw mounted thereon, a protecting-head pivoted above the saw, a counterbalancing-weight thereon, and a device attached to the head and moved, when the head is raised, into position to prevent the feeding of work to the saw, substantially as described.

2. The combination of a saw-blade, a saw mounted thereon, a curved head pivoted above the saw, an extension of the head beyond the pivot thereof, a counterweight on said extension, and a curved rod secured to the extension to prevent the feeding of work to the saw when the head is raised, substantially as described.

698,864. APPARATUS FOR DISTRIBUTING HYDROCARBON UNDER PRESSURE TO HYDROCARBON-LAMPS. JAMES C. BRADY, St. Louis, Mo. Filed Apr. 27, 1900. Serial No. 14,915. (No model.)

Claim.—In an apparatus for distributing hydrocarbon to street-lamps, the combination with a plurality of street-lamps the base of one of which constitutes a chest provided with two compartments arranged one above the other, of a hydrocarbon-tank and a fluid-pressure tank arranged in said compartments, the fluid-pressure tank being detachably connected to the hydrocarbon-tank and removable from the chest, a service-pipe leading from the hydrocarbon-tank to the several lamps, and means for conveying fluid-pressure from the pressure-tank to the hydrocarbon-tank in regulated quantities to force the hydrocarbon to the several lamps, substantially as described.

698,865. SPRING-SEAT. JOHN J. BRADLEY, Fallman, Ill. Filed Apr. 12, 1901. Serial No. 55,725. (No model.)

Claim.—1. In a spring-seat, the combination with the main frame, of the lower flat metal springs, the upper flat metal springs, the ends of the upper springs having eyes formed thereon, and the upper frame supported and held in the said eyes, and the springs arranged between the upper and lower flat springs, and connected thereto, substantially as described.

2. A spring-seat comprising a main frame, the lower flat metal springs connected thereto, the upper flat metal springs, the intermediate coil-springs connecting the upper and lower flat springs, the upper springs having eyes at their ends and dovetail-shaped portions adjacent to said ends, the lower flat springs each having a dovetail-shaped portion at its center, and the upper frame, supported in the eyes at the ends of the upper flat springs.

698,866. FIRE-WATER HEATER AND FURNACE. ISAAC BRONK, Pittsburgh, Pa. Filed May 12, 1900. Serial No. 714,818. (No model.)

Claim.—An improved article of manufacture, a water heater and furnace consisting of a cylinder F, open at one end and closed at the other, having a series of perforations H, the hangers F, said hangers being essentially U-shaped and having their upper ends hooked or bent to engage the boiler-ends, and a pipe I leading into the closed end of the cylinder above the bottom, substantially as above and described.

698,868.

698,867. CYCLE-HANDLE. JOHN E. BROWN and JOHN HARR, Birmingham, England. Filed Nov. 28, 1901. Serial No. 62,451. (No model.)

Claim.—A pillar attachment-clip having washers grooved to receive the flanges of the handle, said washers having resilient extensions also grooved to receive said flanges, and means for holding the washers in place.

698,868. FOLDING BED. CYRIL F. BROWN, Springfield, Mich. Filed May 4, 1901. Serial No. 55,726. (No model.)

Claim.—1. In a folding bed, the combination with a head-frame having feet, a transverse base-plate on said feet, and a bracket-plate extended from the base-plate over its center, of an auxiliary base-plate which is pivoted by one end on the bracket-plate to receive vertical or horizontal adjustment, and a spring-controlled latching device adapted to hold the auxiliary base-plate in upright or lowered position.

2. In a folding bed, the combination with an upright head-frame, of a base, a double-flanged bracket-plate projected from the base proper, an auxiliary base-plate joined upon the flange of the bracket-plate, and a

latching device adapted to hold the auxiliary base-plate upright or in lowered position.

3. In a folding bed, the combination with an upright head-frame, of a base, a bracket-plate having two spaced upright flanges, one of said flanges having a hook-end on one end and a notch in the upper edge spaced from the hook-end, an auxiliary base-plate pivoted at one end between the upright flanges, and a spring-pressed latch-bar pivoted on the auxiliary base-plate and adapted to engage beneath the hook-end when the base-plate is lowered, and enter the notch when said auxiliary base-plate is elevated.

4. In a folding bed, the combination with a head-frame, a fixed base therefor, and an auxiliary base-plate, comprising a U-shaped bar, a bracket-plate projected from the fixed base between sides of the head-frame and whose journal ends of the U-shaped bar are pivoted, and means to hold said U-shaped bar upright or lowered, of a cross-frame, vertically engaged near one end with portions of the head-frame, and a support for the other end of the cross-frame.

5. In a folding bed, the combination with an upright head-frame having two side posts, a bracket-arm extended from each of the side posts, a fixed base for the head-frame, an auxiliary base-plate projected from the fixed base between the side posts of the head-frame, and means for releasably holding the auxiliary base-plate upright or lowered, of a cross-frame pivoted near one end thereof between and upon the bracket-arm, a support at the rear end of the cross-frame having two legs adapted to extend into and rest upon the side posts of the head-frame for its support, when it is lowered, or to be folded up against the lower side thereof when said cross-frame is given an upright position.

6. In a folding bed, the combination with an upright head-frame having feet, two side posts, two bent base-bars on the side posts, arms on the post engaged by upper ends of the base-bars which are offset at lower ends to the feet, a cross-frame pivoted near one end thereof upon the arms of the head-frame, and means for supporting the other end of the cross-frame when it is lowered, of a rectangular counterbalance-frame held to rest on the upper end of the head-frame, and a roller-frame loosely engaging the members of the counterbalance-frame, and having a member extended beneath the cross-frame, so as to contact with the bent base and be guided thereby, and the rocking movement of the cross-frame transmitted to the counterbalance-frame whereby said frame are adapted to fold toward each other or the reverse.

7. In a folding bed, the combination with an upright head-frame, a cross-frame pivoted near one end on the members of the head-frame, and means to support the other end of the cross-frame when it is lowered, of a rectangular counterbalance-frame held to rest on the upper part of the head-frame, a counterbalance-arm on one side of the counterbalance-frame, an adjustable weight-block thereon, and a roller-frame loosely engaging members of the counterbalance-frame and cross-frame for their simultaneous movement toward or from each other.

698,869. COMBINED PICTURE-KIMNOCK AND PHOTOGRAPH. THOMAS F. BROWN, Denver, Colo. Filed Dec. 12, 1901. Serial No. 55,727. (No model.)

Claim.—1. In an apparatus of the class described, the combination with a photograph or similar instrument capable of repeating or reproducing recorded speech or sound, of means for bringing successively into view at predetermined intervals, a series of pictures illustrative of the subject-matter of the repeated record, an electric motor connected with said picture-displaying means, a normally open circuit, a series of electrodes or contacts adjustably mounted on a stationary part of the instrument, located in the motor-circuit and arranged to close the circuit through a moving part of the photograph, substantially as described.

2. In an apparatus of the class described, the combination with a photograph or similar instrument, of means controlled from a traveling arm of the photograph-carriage for successively displaying pictures or views illustrative of the repeated record.

3. In a picture-exhibitor, the combination with a photograph or similar instrument, and a stereoscope, of means controlled from a traveling arm of the photograph-carriage for bringing a series of pictures or views illustrative of the repeated record, successively into position to be viewed through the stereoscope at predetermined intervals, substantially as described.

4. In a picture-exhibitor, the combination with a photograph or similar instrument capable of repeating recorded speech or sound, and a stereoscope arranged in suitable proximity to said instrument, of means controlled from a moving part of the photograph-carriage for successively bringing a series of pictures or views illustrative of the repeated record into position to be viewed through the stereoscope, at predetermined intervals.

5. The combination with a photograph or similar instrument, of a picture-carrier mounted in suitable proximity to the instrument, and means

controlled from the carriage of the instrument for actuating the carrier at predetermined intervals.

6. The combination with a photograph or similar instrument, of a picture-carrier normally locked against movement, means controlled by a moving part of the photograph-carriage for unlocking the carrier, and means also controlled by a moving part of the photograph for actuating the picture-carrier at predetermined intervals.

7. The combination with a photograph or similar instrument, of a normally locked picture-carrier, means controlled from a moving part of the photograph for unlocking the carrier, means also controlled by a moving part of the photograph for actuating the carrier, and means controlled by the moving carrier, for locking the latter against movement when it has traversed a predetermined distance.

8. The combination with a photograph or similar instrument, of a picture-carrier mounted to move in suitable proximity thereto, an electric motor connected to operate said carrier, a normally open motor-circuit, and means mounted on the carriage of the photograph for closing said circuit at predetermined intervals.

9. The combination with a photograph or similar instrument, of a picture-carrier mounted to move in suitable proximity to the instrument, and an electric motor controlled from the photograph-carriage, for actuating the carrier at predetermined intervals.

10. The combination with a photograph or similar instrument, of a picture-carrier, an electric motor connected to operate said carrier, a motor-circuit controlled by a moving part of the photograph, a carrier-locking device, an electromagnet whose structure is connected with said device, and a magnet-circuit arranged to be controlled by a moving part of the photograph.

11. The combination with a photograph or similar instrument, of a picture-carrier mounted in suitable proximity to said instrument, an electric motor connected to operate said carrier, a normally open motor-circuit, an electromagnet arranged when energized to close the motor-circuit, and a magnet-circuit controlled by a moving part of the photograph.

12. The combination with a photograph or similar instrument, of a picture-carrier arranged in suitable proximity thereto, an electric motor connected to operate the carrier, a normally open motor-circuit, and a number of electrodes or contacts adjustably mounted and located to the motor-circuit, and arranged to close the circuit through a moving part of the photograph.

13. The combination with a photograph or similar instrument, of a picture-carrier, an electric motor connected to operate the carrier, a normally open circuit, and a number of electrodes or contacts adjustably mounted and located to the motor-circuit, and arranged to close the circuit through a moving part of the photograph.

14. The combination with a photograph or similar instrument, of a picture-carrier arranged in suitable proximity to the photograph, an electric motor connected to operate said carrier, a normally open motor-circuit, a series of electrodes or contacts adjustably mounted and lying in said circuit, and a part connected to move with a moving part of the photograph.

for successively engaging said electrodes and closing the motor-circuit, substantially as described.

15. The combination with a phonograph or similar instrument, of a picture-carrier mounted in suitable proximity to the phonograph, an electric motor connected to operate said carrier, a normally open motor-circuit, an electromagnet arranged when energized to close the motor-circuit, a magnet-circuit, a part connected with a moving part of the phonograph, and a series of electrodes or contacts lying in the path of said magnet-circuit and arranged to successively close the magnet-circuit.

16. The combination with a phonograph or similar instrument, of a picture-carrier arranged in suitable proximity thereto, an electric motor connected to operate the carrier, a normally open motor-circuit, a carrier-locking device, an electromagnet for operating said device, and a normally open magnet-circuit, the two circuits being arranged to be alternately closed by a moving part of the phonograph.

17. The combination with a phonograph or similar instrument, of a picture-carrier, an electric motor connected to operate the carrier, a motor-circuit, a locking device for the carrier, an electromagnet connected to operate the carrier-locking device, a magnet-circuit, a series of electrodes or contacts located in the motor-circuit, another series of electrodes or contacts located in the magnet-circuit, and means connected with a moving part of the phonograph for alternately and successively engaging the electrodes or contacts of the two circuits whereby the circuits are closed, substantially as described.

18. The combination with a phonograph or similar instrument, of a picture-carrier mounted in suitable proximity to the said instrument, an electric motor connected to operate the carrier, a normally open motor-circuit, a metal strip insulated from the phonograph and lying in the motor-circuit, a series of electrodes or contacts adjustably connected with said strip, and a dental brush connected with a moving part of the phonograph and adapted to successively engage said electrodes or contacts, whereby the circuit is closed at predetermined intervals, substantially as described.

19. The combination with a phonograph or similar instrument, of a picture-carrier, an electric motor connected to operate said carrier, a normally open motor-circuit, a carrier-locking device, an electromagnet for operating said device, a normally open magnet-circuit, two metal strips insulated from the phonograph, a series of electrodes or contacts adjustably connected with each strip, and a part connected with a moving part of the phonograph and adapted to engage both series of contacts or electrodes, whereby the circuits are closed through the moving part of the phonograph, substantially as described.

20. The combination with a phonograph or similar instrument, of an endless carrier mounted in suitable proximity to the instrument, picture-holding frames mounted thereon, an electric motor geared to the carrier in operative relation, and a normally open motor-circuit, arranged to be closed through a moving part of the phonograph-carriage at predetermined intervals.

21. The combination with a phonograph or similar instrument, and a stereoscope, of an endless carrier, mounted in suitable proximity to the phonograph, and in front of the stereoscope at the proper focal distance, an electric motor connected to operate the carrier, and a normally open motor-circuit arranged to be controlled by a moving part of the phonograph-carriage, substantially as described.

22. The combination with a phonograph or similar instrument, of a carrier composed of two endless chains, sprocket-wheels which the chains engage, and a series of picture-holding frames connected with the chains and spanning the space between the same, an electric motor geared to one of the sprocket-wheels to operate the carrier, and a normally open motor-circuit arranged to be closed at predetermined intervals by a moving part of the phonograph-carriage.

23. The combination with a phonograph or similar instrument, of a carrier mounted in suitable proximity thereto and composed of endless chains mounted on sprocket-wheels, an electric motor connected to operate the carrier, a normally open motor-circuit, an electromagnet, a carrier-locking device, comprising a bar, spring-held to project into the path of a part of the carrier whereby the latter is held against movement, the said bar being connected with an armature of the magnet and arranged to be withdrawn out of the path of the moving part of the carrier when the magnet is energized, a device for locking the bar in the withdrawn position, and a trip-lever connected with said device and projecting into the path of the carrier, whereby a part of the carrier engages the trip-lever and releases the spring-held locking-bar at predetermined intervals, substantially as described.

24. The combination with a phonograph or similar instrument, of a picture-carrier, and a motor connected to operate the carrier, said motor being independent of the motor or operating mechanism of the instrument, and controlled from the phonograph-carriage.

25. In an apparatus of the class described, the combination with a phonograph or similar instrument, of a picture-carrier, an electric motor

connected to operate the carrier, said motor being independent of the motor or operating mechanism of the instrument, a motor-circuit, and a number of electrodes mounted on a stationary part of the instrument, located in the motor-circuit, and arranged to close the circuit through an arm of the carriage of the instrument.

26. The combination with a phonograph or similar instrument, of a picture-carrier, an electric motor connected to operate the carrier, said motor being independent of the motor or operating mechanism of the instrument, a series of separated electrodes or contacts mounted on a stationary part of the instrument, and a part traveling with the carriage of the instrument and arranged to successively engage the said electrodes, whereby the motor-circuit is closed at predetermined intervals, substantially as described.

898,870. COMBINED SCALE AND PNEUMOLOG. FREDERICK F. H. BURNER, Louisville, Ky. Filed Sept. 7, 1901. Serial No. 74,048. (No model.)

Claim.—1. In a weighing device, the combination with a truncated tubular holder, and a two-part case, one part slidable on the other and having graduation thereon, of a slide-bar supported in one case-portion so as to slide and project from one end of the holder, a spring adapted to support the slide-bar and yield when weight is applied to the projected end of said bar, and means to detachably connect the article to be weighed with the said extended end of the bar.

2. In a weighing device, the combination with a truncated tubular holder, and a two-part telescopic case therein, one part of said case having graduation on it, of a slide-bar, a core-tube through which said bar slides, a spring encircling the core-tube and engaging its ends respectively with a flange on the core-tube and with one section of the case, and means to detachably connect the article to be weighed with an end of the slide-bar.

3. In a weighing device, the combination with a truncated tubular holder adapted to receive a pan at one end, and a two-part telescopic case therein, one section of the case having graduation thereon, of a slide-bar, a core-tube flanged at one end and contracted at the opposite end, a coiled spring encircling the core-tube and engaged at its ends respectively with the flange in the core-tube and with a flange on one section of the case, two resilient flaps formed on one portion of the slide-bar adapted to grip an article to be weighed when said flaps are extended from the holder, and means to hold the slide retracted.

4. In a weighing device, the combination, with a truncated tubular holder adapted to receive a pan at one end, and a two-part telescopic case therein, one section of said case having graduation thereon, of a slide-bar slotted at one end and having tabs extending on the free ends of the slide-bar, a keeper-bar in one section of the case, adapted to receive and detachably hold the fingers, a core-tube through which the slide-bar may reciprocate, said tube having a radial flange at one end, and a coiled spring encircling the core-tube and engaged at its ends respectively with the radial flange and with an internal flange on one end of one case-portion.

898,871. CONTAINER WITHIN FRAMES AND HOOD. WILLIAM A. BURNHART, Louisville, Ky., assignor of one-half to George R. Cooper, Louisville, Ky. Filed Nov. 27, 1901. Serial No. 88,594. (No model.)

Claim.—1. The combination with a removable swing-frame, of brackets removably secured on the frame, and a hood mounted on the brackets.

2. The combination with a removable swing-frame, comprising two side bars joined by a top cross-bar, of brackets removably secured on the side bars of the frame, and a hood mounted on the brackets.

3. In an swing-frame, the combination with the side bars of the frame that are joined together by a top cross-bar, of means for removably securing said side bars upon a window-cumment, comprising a slidable cleave mounted upon each side bar, a knob projected from the side of each cleave by an intervening neck, a keeper-plate for each knob secured on the side of the window-cumment, and having a keyhole-slot therein into which the knobs may enter and engage their spacing-necks with edges of the slots, thus adapting the knobs to detachably secure the side bars of the frame on the cumment, and a clamping device for the lower portion of each side bar.

4. An swing-frame, comprising side bars bent outward and upward at their upper ends, a cross-bar integral with said ends, a cleave on each side bar having a knob thereon spaced from the cleave by a neck, a keeper-plate for each knob, having a keyhole-slot therein which may be engaged by the knob and neck, a substantially U-shaped frame-bar hinged on cleaves mounted to slide on the side bars, and a bracket-block for each side bar, having a perforated base, said bases receiving the side bars, and a set-screw for each base, adapted to secure a side bar therein.

5. In a device of the character described, the frame having side bars joined by a spacing cross-bar, brackets mounted on the side bars near the cross-bar, and a plate-like hood secured by its ends on the brackets and extended above the cross-bar.

898,872. LIFTING-JACK FOR CARS. DR. HOWARD B. GRAY, Philadelphia, Pa., assignor of three-fourths to William F. Sheworth, Dr. Wm. Sheworth, and Anna Stark, Philadelphia, Pa. Filed Dec. 27, 1901. Serial No. 87,488. (No model.)

Claim.—1. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto provided with supporting-wheels, and

and means adapted to be actuated by the car-wheel for drawing the arms inwardly to raise the truck.

2. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto provided with supporting-wheels, arms secured to the arms, and a threaded shaft engaging the nuts, with means adapted to be actuated by the car-wheel for turning the shaft.

3. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto provided with supporting-wheels, arms secured to the arms, a threaded shaft engaging the nuts, and gearing for rotating the shaft adapted to be actuated by the car-wheel.

4. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto provided with supporting-wheels, arms secured to the arms, a threaded shaft engaging the nuts provided with a worm-wheel, and a shaft provided with a worm engaging the worm-wheel, with means for turning the shaft adapted to be actuated by the car-wheel.

5. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto provided with supporting-wheels, arms secured to the arms, a threaded shaft engaging the nuts, and gearing for rotating the shaft adapted to be actuated by the car-wheel.

6. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto provided with supporting-wheels, arms secured to the arms, a threaded shaft engaging the nuts provided with a worm-wheel, a worm engaging the worm-wheel and provided with a disk adapted to be turned by contact with the car-wheel, and means for exerting inward pressure of the disk against the car-wheel.

7. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto provided with supporting-wheels, means adapted to be actuated by friction of the car-wheels for moving the arms to raise the truck, and means for exerting inward pressure of such frictionally-actuated means against the car-wheel.

8. Lifting mechanism for cars, consisting of a truck-bearing frame, arms pivoted thereto having bearing-terminals adapted to move along a bearing-bar, arms secured to the arms, a threaded shaft engaging the nuts provided with a worm-wheel, a worm engaging the worm-wheel, and means adapted to make frictional contact with the car-wheel for actuating the worm.

898,873. INCANDESCENT GAS-BURNER. FREDERICK R. CLAYTON, Newark, and GEORGE C. BURGESS, Orange, N. J., assignors of one-third to Augustus Kolbensch, Newark, N. J. Filed Dec. 17, 1901. Serial No. 88,578. (No model.)

Claim.—1. In an incandescent gas-burner, a connection fitted to the gas-supply pipe, and provided with longitudinal cuttings, a valve-seat secured to the upper end of said connection, a needle extend-

ing longitudinally through the upper portion of said connection, and means fitted within an aperture in the connection, said connection to the needle, for moving said needle toward and from the valve-seat, substantially as described.

2. In a Bunsen gas-burner, a needle-valve comprising an apertured connection, a valve-seat secured to said connection, a needle extending through the upper end of said connection, the lower end of said needle being threaded, and an adjusting-screw seated in an aperture in the connection and fitted to the threaded end of the needle, for operation, substantially as described.

2. In a gas-burner, a connection fitted upon the gas-supply pipe and provided with longitudinal outlet-springs, a valve-seat secured to the upper end of said connection and provided with a control control, a needle fitted to slide centrally in the connection, and a milled adjusting-screw for moving the needle toward and from the valve-seat, substantially as described.

4. In a Deason gas-burner, a connection provided with longitudinal outlet-spouting, a valve-seat covered to the upper end of said connection, a valve-needle extending up through the connection, the lower end of said needle being threaded, an adjusting-nut fitted to the threaded end of said needle and seated in an aperture in the connection, recesses at the sides of the connection to permit access to the nut, and a Deason tube above the connection, substantially as described.

698,874. TOOTH AND RAMP FOR PROSPERATE-LOOSE. RALPH
E. GARR, Ocala, Fla., assignor to the Ocala Foundry and Machine
Works, Ocala, Fla. Filed Nov. 23, 1901. Serial No. 22,702. (No model.)

Claim.—1. As an article of manufacture, a device of the kind described, comprising a base-plate provided with a recess having substantially the shape of a double wedge and also provided with cylindrical apertures merging into said recess, a tooth provided with an enlarged portion having substantially the shape of a double wedge and also provided with cylindrical apertures mating said apertures of said base-plate, and cylindrical parts of resilient material, for detachably engaging all of said apertures.

2. As an article of manufacture, a base-plate having a recess provided with overhanging walls, said walls having oppositely-disposed conical cylindrical apertures diverging from each other, a tooth provided with an enlarged portion having substantially the shape of a double wedge for engaging said recess and also provided with conical cylindrical apertures diverging from each other and engaging said conical cylindrical apertures of said walls, means for securing said base-plate to a leg, and cylindrical posts to be driven into said conical cylindrical apertures.

2. As an article of manufacture, a device of the kind defined, comprising a base-plate provided with an angular band adapted to fit the contour of an angular leg, and also provided with a recess, a raised band extending across said recess adjacent to said band and flush with the bottom of said recess so as to form a continuation of said bottom, a tooth provided with a substantially wedge-shaped portion for engaging said recess, and means for securing said tooth within said recess.

698,875. STOPPER DEVICE FOR STATIONARY WAREHOUSES.
HERMAN E. COLLIER, Denver, Colo. Filed May 12, 1902. Serial No.
59,912. (No model.)

Claim.—1. The combination with a basin having a discharge opening, a stopper for the opening, and a sleeve forming a seat for the stop-

par, of a lever connected with the stopper at its lower extremity, and a fulcrum arm connected with the sleeve and projecting upwards along the interior wall of the basin, and curved to conform to the interior wall of the basin, the lever being fulcrumed at the upper extremity of said arm, the arrangement being such that when the upper arm of the lever is pushed outwardly, the lower arm moved on its fulcrum and its lower end extended to open the stopper or diaphragm.

2. The combination with a wassuph, having a discharge-opening, a stopper for the opening and a sleeve forming a seat for the stopper, of an arm connected with the sleeve, extending upwards therefrom and curved to conform to the shape of the inner wall of the wassuph, a lever fulcrumed on said arm one extremity of the lever being connected with the stopper, and a slotted plate hinged at the top of the basin and adapted to receive the upper extremity of the lever, the said plate being shaped to hold the lever in either position of adjustment.

8. The combination with a stationary workbench, a stopper for the discharge-opening, and a device turning a coat for the stopper, of an arm detachably connected with the above and held in place thereby, the said arm projecting upwardly along the bench-wall, a lever fulcrumed on said arm, the lower arm of the lever being connected with the stopper, and a dotted plate through which the upper extremity of the lower passage, said plate being secured to the stationary structure at the top of the basin, projecting interiorly over the edge thereof and fashioned to leak the lever in either position of adjustment.

4. The combination with a stationary workbasin, a stopper for the discharge-opening, and a sleeve forming a seat for the stopper, of a ring surrounding the sleeve and engaged from above by the flange of the sleeve, the said ring being formed with an upwardly-projecting arm, and a lever fulcrumed on said arm and connected with the stopper to operate the latter when the upper arm of the lever is moved.

5. The combination with a stationary washbasin, a stopper for the discharge-opening, and a sleeve forming a seat for the stopper, of an arm detachably connected with the sleeve and held in place thereby, the said arm projecting upwardly along the basin-wall, and a lever fulcrumed on said arm, the lever arm of the lever being connected with the stopper, and the arrangement being such that the stopper is opened and closed by the outward and inward movement of the upper arm of the lever.

698,878. MOTOR-VEHICLE FRAME WALTER A. GROUTEN
Chicago, Ill. Filed June 26, 1901. Serial No. 46,941. (No model.)

Claim.—1. A vehicle gear or underframe comprising front and rear transverse frame members, a reach carried to the front transverse frame member and terminating in front of the rear transverse frame member, trans-rod or struts which connect said rear transverse frame member with the reach at a distance from its rear end and a transverse brace which connects the rear end of said reach with said trans-rod or struts, substantially as described.

2. In a motor vehicle, the combination of front and rear transverse frame members, a cross member secured to the front transverse frame member and terminating in front of the rear transverse frame member, front-side or struts which connect said rear transverse frame member with said cross member and a motor secured to the rear end of the cross member and to the rear transverse frame member, substantially as described.

3. In a motor-vehicle, the combination of front and rear transverse frame members, a rear control to the front transverse frame member and terminating in front of the rear transverse frame member, trans-axle or axle which connect said rear with said rear transverse frame member with said rear and a motor coupled to the rear end of the rear and to the rear transverse frame member, substantially as described.

4. A vehicle gear or underframe comprising front and rear trans-

verse frame member, a reach secured to said front frame member and terminating in front of said rear frame member and trans-rod or struts which connect said reach with said front and rear transverse frame members at points out of line vertically with said reach, substantially as described.

h. A vehicle gear or underframe comprising a rear-axle support, a central shaft which terminates in front of said rear-axle support; diagonal struts or trans-axle which connect said rear-axle support at or adjacent to its end with a head on said shaft, a front axle pivoted to said shaft, and diagonal struts or trans-axle which connect said front axle at or adjacent to its end with a head revolvably secured to said shaft, substantially as described.

2. A vehicle gear or underframe comprising a rear-axle support, a central ranch which terminates in front of said rear-axle support, diagonal struts or trans-axle which connect said rear-axle support at or adjacent to its ends with said ranch, a brace which connects said ranch adjacent to the rear end with said struts or trans-axle, a front axle pivoted to said ranch and diagonal struts or trans-axle which connect said front axle at or adjacent to the ends with a band revolvably secured to said ranch, substantially as described.

698,877. WRENCH. HARRISON BOWEN, Columbia Falls, Mont.
Filed Aug. 2, 1901. Serial No. 71,381. (No model.)

Chin.—Is a wrench, the combination with a chuck provided with work-teeth and a fixed jaw, of a movable jaw mounted to slide upon said chuck and provided with a chamber open at both ends, said movable jaw being provided at its rear end with an apertured-projecting dotted extension, a spindle journaled to the side walls of said chamber at a point within the chamber and having its outer end projecting into the dotted extension and guided thereby, a spring biased within said chamber and surrounded by the walls thereof and exerting its energy to force the spindle toward the chuck, and a worm journaled on said spindle between the dotted extension and the inner open end of the chamber, whereby when the jaw 4 is moved into contact with the jaw 3, both ends of the chamber will be closed to prevent the admission therein of foreign matter or objects, substantially as set forth.

698,878. GUIDE FOR STAMP-OUTING. DAVID C. DUNNAGE.
 Appleton Cent. Co. First Apr. 8, 1901. Serial No. 84,806. (No model.)

Claim.—A guide for battery-stamp stems consisting of a casting secured to the battery-stems above the stamp or line of stamps, and formed with a tapering neck or opening through the casting above each stamp, and with a passage through the front wall of each neck for the lateral admission or removal of the stamp-stem, a notched tapering sleeve or shell fitted around each stem and adapted to fit and cut itself in the neck in the casting, and a key on the sleeve or shell adapted to project through the opening in front of the neck, substantially as described.

698,879. CANE-PRESSING MECHANISM FOR CANE-MILLS.
FRANCISCO BLANCO, Chucho de Pueblo Nuevo, Cuba. Filed Oct. 2,
1901. Serial No. 77,400. (No model.)

Claim.—1. A feeding device, comprising a first conveyor, means for actuating the same, a movable frame carrying said conveyor and arranged to change its position according to the load resting on the conveyor, a second conveyor arranged to discharge the material on the first conveyor, a driving mechanism connected with the second conveyor, a controlling device for throwing said driving mechanism into or out of action, and an operative connection for governing the position of said controlling device according to the movement of the frame of the first conveyor.

2. The combination of a first conveyor, a movable frame carrying said conveyor, counterbalancing means for governing the position of the frame according to the load resting thereon, means for driving the first conveyor, a second conveyor arranged to discharge the material upon the first conveyor, driving mechanism connected with the second conveyor, a controlling device governing the action of said driving mechanism, and an operative connection from the movable frame to the said controlling device.

2. The combination of a first conveyor having at one of its ends a shaft journaled in stationary bearings, a conveyor-frame pivotedly hinged on said shaft and provided at its free end with bearings for the shaft at the other end of the conveyor, a second conveyor arranged to discharge material upon the first conveyor, a driving mechanism for the second conveyor, a controlling device governing the action of the said driving mechanism, and an operative connection from the swinging conveyor-frame to the said controlling device.

898,880. DOUBLE DOOR. Otto FRANKZ, Freiburg, Germany.
Filed May 24, 1931. Serial No. 61,745. (No model.)

Obtain.—A pair of doors having a pair of slides one secured to each door which are situated in the same plane and whose width are greater than half the distance between the two doors, the face of each slide being provided with a room for the passage of the face of the other slide, substantially as set forth.

698,881. **THREAD-POWER.** CHARLES R. GALE, Minneapolis, Minn.
Filed Jan. 16, 1898. Serial No. 59,289. (No model.)

Claim.—1. An animal-tread power, embodying a cylinder, the interior circumferential wall of which constitutes an endless track upon which the animal walks, and the exterior circumferential wall of which constitutes endless frictional contact; horizontal rollers, upon which the said cylinder is mounted and upon which it is rotated, and pillow-blocks within which the said rollers are journaled, the whole constituting a friction-gear wherein the cylinder imparts a rotary movement to the rollers, substantially as shown and described.

2. An animal-tread power, embodying a cylinder within which the animal walks; rollers upon which the said cylinder is mounted, and a frame supporting the said rollers, whereby, when the said cylinder is rotated, a rotary movement will be imparted to the said rollers through frictional contact therewith, substantially as shown and described.

3. In an animal-tread power, the combination of the frame consisting of side and cross-ties, pillow-blocks rigidly affixed to the said frame, bases adjustably affixed to the said pillow-blocks, shafts journaled in the said bases, rollers affixed to the said shafts, and a drum mounted upon the said rollers, the interior of said drum constituting an endless track upon which the animal walks, thereby rotating the same, and transmitting through frictional contact, a rotary movement to the said rollers, substantially as shown and described.

698,882. **CORN-PLASTER.** HARRY L. CHANDLER, Doverport, Iowa. Filed Mar. 25, 1891. Serial No. 62,514. (No model.)

Claim.—1. The combination of the wheel-frame, the axle to which the wheel-frame is rigidly attached, wheels loosely journaled on the axle, an outer clutch member having teeth cut diagonally and secured around the axle to the hub of a wheel, an inner clutch member having teeth cut diagonally, a sleeve having a peripheral groove and a sprocket-wheel, a bracket having a hollow arm and secured to the sleeve of the inner clutch member and the bracket, a rod extending through the hollow arm of the bracket and having a yoke engaging the peripheral groove of the inner clutch member, the main lever having an arm, a flexible connection between the rod and the arm on the main lever, a runner-frame, an operating-shaft having a sprocket-wheel and carried by the runner-frame, and a sprocket-chain connecting the sprocket-wheels.

2. The combination of the wheel-frame, the axle to which the wheel-frame is rigidly attached, wheels loosely journaled on the axle, an outer clutch member having teeth cut diagonally and secured around the axle to

the hub of a wheel, an inner clutch member having teeth cut diagonally, a sleeve having a peripheral groove and sprocket-wheel, a bracket having a hollow arm and secured to the wheel-frame, a coil-spring surrounding the axle between the sleeve of the inner clutch member and the bracket, a rod extending through the hollow arm of the bracket and having a yoke engaging the peripheral groove of the inner clutch member and a step to limit the forward movement of the rod, the main lever having an arm, a flexible connection between the rod and the arm on the main lever, a runner-frame, an operating-shaft having a sprocket-wheel and carried by the runner-frame, and a sprocket-chain connecting the sprocket-wheels.

3. The combination of the wheel-frame, the axle to which the wheel-frame is rigidly attached, wheels loosely journaled on the axle, outer clutch members each having teeth cut diagonally and secured around the axle to the hub of the wheel, inner clutch members each having teeth cut diagonally, a sleeve having a peripheral groove and a sprocket-wheel, brackets each having a hollow arm and secured to the wheel-frame, coil-springs surrounding the axle between the sleeve of the inner clutch members and the brackets, rods extending through the hollow arms of the brackets each having a yoke engaging a peripheral groove of an inner clutch member, the main lever having an arm, a flexible connection between the rods and the arm on the main lever, a runner-frame, an operating-shaft having sprocket-wheels and carried by the runner-frame and sprocket-chains connecting the sprocket-wheels.

4. A corn-plaster comprising a wheel-frame, and a runner-frame connected together, an axle on which the wheel-frame is mounted, wheels in which the axle is journaled, outer clutch members having slanting teeth and fixed to the wheel, inner clutch members having slanting teeth and peripheral grooves and loosely mounted on the axle, an operating-shaft mounted on the runner-frame, brackets having hollow arms and secured to the wheel-frame, coil-springs surrounding the axle between the inner clutch members and the brackets, rods extending through the hollow arms and having yokes engaging the peripheral grooves of the inner clutch members, the main operating-lever having a depending arm and mounted on the wheel-frame, a flexible connection whereby the rods and the main operating-lever are connected and gearing whereby the inner clutch members are connected with the operating-shaft.

5. The combination of the wheel-frame, a runner-frame, an operating-shaft mounted on the runner-frame, means for rotating the operating-shaft, the leg having a pin and secured to the operating-shaft, the rock-shaft, the arm fixed on the rock-shaft having a head with which the pin engages and a pendulum hook, a spring connecting the hook with the runner-frame, a pendulum arm secured to the rock-shaft, the depending support secured to the runner-frame, the marking-lever provided with a marking-prong and pivoted to the depending support and the link whereby the pendulum arm and the marking-lever are connected.

6. A corn-plaster comprising a wheel-frame and runner-frame connected together, an axle, the outer clutch members, the inner clutch members, having sprocket-wheels and peripheral grooves, springs bearing against the inner clutch members the operating-shaft mounted on the runner-frame, the sprocket-wheel secured on the operating-shaft, a radial arm provided with a pin and secured on the operating-shaft, the rock-shaft, the arm provided with a head and a hook, and secured to the rock-shaft, the pendulum arm secured to the rock-shaft, the spring connected to the hook, and to the runner-frame, a depending support secured to the runner-frame, the marking-lever having a marking-prong and pivoted to the depending support, the link whereby the pendulum arm and the lever are connected, brackets secured to the wheel-frame, rods having forks fitting the peripheral grooves, the main lever, having an arm and mounted on the wheel-frame, and a flexible connection between the rods and the arm of the main lever.

7. A corn-plaster comprising a wheel-frame, and a runner-frame connected together, an axle on which the wheel-frame is mounted, wheels in which the axle is journaled, outer clutch members having slanting teeth and fixed to the wheel, inner clutch members having slanting teeth and loosely mounted on the axle, an operating-shaft mounted on the runner-frame, means whereby the members of the clutches are placed in and out of gear, gearing whereby the inner clutch members are connected with the operating-shaft, a marker-support depending from the runner-frame, a lever having a marking-prong, at its rear end and fulcrumed to the support, the leg having a pin and secured to the operating-shaft, the rock-shaft located beneath the operating-shaft, the arm mounted on the rock-shaft having a head with which the pin engages and a pendulum hook, a spring whereby the hook is connected with the runner-frame, a pendulum arm secured to the rock-shaft, and the rod whereby the pendulum arm is connected with the front end of the marking-lever.

8. A corn-plaster comprising a wheel-frame, and a runner-frame connected together, an axle on which the wheel-frame is mounted, wheels in which the axle is journaled, outer clutch members having slanting teeth and fixed to the wheel, inner clutch members having slanting teeth and

loosely mounted on the axle, an operating-shaft mounted on the runner-frame, means whereby the members of the clutches are placed in and out of gear, gearing whereby the inner clutch members are connected with the operating-shaft, a hopper-frame having a leg through which the end of the operating-shaft extends, a hopper having a discharge-opening and a bottom plate having a feed-opening, a feed-plate between the bottom plate and the discharge-opening, gearing whereby the feed-plate is connected with the operating-shaft, a feed-tube, a bell-crank lever, a bolt whereby the bell-crank lever is pivoted to the feed-tube, an upper valve secured to one arm of the bell-crank lever, a lower valve pivoted to the feed-tube, the rock-shaft, means connected with the operating-shaft whereby the rock-shaft is actuated, the bell-crank lever fixed to the bolt of the first-named bell-crank lever, the arm fixed to the rock-shaft, a link whereby the arm on the rock-shaft is connected with one arm of the second-named bell-crank lever, and the link whereby the lower valve is connected with the other arm of the second-named bell-crank lever.

698,888. **ELECTRIC-CIRCUIT-CLOSING DEVICE.** FREDERICK WILDER, Akron, Ohio, assignor of three-fourths to John G. Fisher, Smith & Tish, and Louis A. Wood, Akron, Ohio. Filed June 25, 1899. Serial No. 71,148. (No model.)

Claim.—1. In an electric-circuit-closing device, means to keep the circuit open consisting of a contact-spring and a circuit-closing point to be engaged by said spring, a plunger operatively engaged with said contact-spring, a pair of spring-arms and a part engaged at its ends by said arm and at its middle by said plunger, substantially as described.

2. In an electric-circuit-closing device, a casing and a circuit-closing spring therein and a contact-point for said spring, a plunger supported and adapted to slide in said casing, a set of spring-arms on said casing and a cross-piece engaged in said spring and serving as a bearing for one end of said plunger, substantially as described.

698,884. **DEVICE FOR SEWING-MACHINE.** WILLIAM E. ARMBRIST, Bridgeport, Conn., assignor to Wheeler & Wilson Manufacturing Company, Bridgeport, Conn., a Corporation of Connecticut. Filed Aug. 1, 1894. Serial No. 78,548. (No model.)

Claim.—1. A needle attachment for sewing-machine, employing an inner guide and an outer casing, and means whereby said guide and casing may be given rotary and longitudinal adjustments, substantially as and for the purpose specified.

2. A needle attachment for sewing-machine, comprising essentially an inner guide and an outer casing spaced apart and rigidly connected, a support therefor, and means whereby said guide and casing may be given a rotary adjustment within said support for turning the binding material equally or unequally on opposite sides of a fabric, and means whereby said guide and casing may be adjusted longitudinally in said support, substantially as described.

3. A needle attachment for sewing-machine, having an inner guide, an outer casing, and a clamp adapted to be secured to the cloth-plate of the sewing-machine, and means whereby the casing may be given rotary and longitudinal adjustments, substantially as and for the purpose specified.

4. A needle attachment for sewing-machine, comprising a casing, a support for said casing, and means whereby the casing may be given a rotary and also a longitudinal adjustment, a case or guide arranged within said casing, and means to fix said case or guide within said casing to portions of its adjustment, substantially as described.

698,885. **WIRE-CLIPPING ELEVATOR-GATE.** GEORGE E. ARMBRIST, Philadelphia, Pa., assignor of one-half to Fairmount Machine Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed June 25, 1892. Serial No. 63,322. (No model.)

Claim.—1. The combination of an elevator-gate, endless chain and

ably mounted and supporting said gate, means for locking the gate, an elevator-car, means carried thereby for releasing the locking mechanism and permitting the closing of the gate by hand said means serving also to engage the chains and return the gate to the closed position as the elevator-car moves away from the floor or landing.

2. The combination of an elevator-gate, endless chain, substantially mounted and supporting said gate, means for locking said gate, projections carried by said chains, an elevator-car, and means carried by said car adapted to release the chain locking mechanism and to engage said projections whereby the chains may be moved to return the gate to its normal position as the elevator-car moves away from the floor or landing.

3. The combination of an elevator-car, a gate for a floor or landing, endless chains suitably mounted and supporting said gate, sprocket-wheels over which said chains pass, a ratchet-wheel carried by one of said sprocket-wheels, a spring-controlled pawl in engagement with said ratchet-wheel, and an arm carried by the elevator-car and adapted to move said pawl out of engagement with the ratchet-wheel, substantially as described.

4. The combination of an elevator-gate, endless chain, substantially mounted and supporting said gate, sprocket-wheels over which said chains pass, a ratchet-wheel carried by one of said sprocket-wheels, a spring-controlled pawl in engagement with said ratchet-wheel, an elevator-car, a cam projection carried by said pawl, and an arm carried by the elevator-car and adapted to engage said cam projection to hold the pawl out of engagement with the ratchet-wheel, substantially as described.

5. The combination of the elevator-gate, endless chain, substantially mounted and supporting said gate, projections on said chains, an elevator-car, yoke-arms carried by said car and arranged to pass on both sides of the chains, said yoke-arms being adjacent to the projections on the chains when the gate is in the raised position, and adapted to engage one set of said projections when the elevator-car moves away from a floor or landing in either direction.

698,886. **SECRET-SERVICE TELEPHONE SYSTEM.** ALBERT E. ARMBRIST, San Francisco, Cal. Filed Jan. 20, 1891. Serial No. 64,548. (No model.)

Claim.—3. Is a telephone system, stations interconnected through individual lines and local circuits, including a line-circuit for each station and a movable contact adapted to connect the primary circuit of the station with the line of a selected station; means controlling the movable contact to hold it normally on the line-circuit of its own station while

the receiver is hung up and to release it for switching when the receiver is taken down; a ringing-circuit common to all the stations connecting one station with another through their respective switching-contacts to form with the interconnecting lines of two stations a metallic circuit including a main battery and a bell and push-button at each station; means controlling the talking or secondary circuit to open and close the same, and itself controlled by the movable contact; and electrically-actuated means in the ringing-circuit between the main battery and the push-button adapted to throw said controlling means out of action when a circuit is completed through the main battery and the circuit of the called station.

2. In a telephone system the combination, with a plurality of stations interconnected through individual line-wires, and switching devices at each station comprising stationary contacts and a movable contact through which the talking-circuit of the station is connected with another selected station; of a ringing-circuit controlling the telephone switch-contacts of the talking or secondary circuit and including a main battery and a push-button at every station, and electrically-actuated means in the ringing-circuit at every station controlling the talking or secondary circuit and means being controlled by the movable contact of the switching device, whereby the primary circuit is broken and held open when the movable contact is moved off the individual line-contact of the station, and is closed when a ringing-circuit can be completed between the two selected stations.

3. In a telephone system containing stations interconnected through local switching devices and line-wires, the combination of means controlling the talking, or secondary, circuit at each station, said means being controlled by the switch device to break or hold open the primary circuit when the switch is moved off its home contact; a ringing-circuit including a main battery and a push-button at each station, by which a circuit is completed through the battery and the bell at the called station; means controlled by the movable contact for breaking said circuit when the movable contact of the station is moved off its line-contact; and means operative electrically from the main battery over the ringing-circuit and line-wires from the calling-station through the called station to throw the controller of the calling-station out of action and restore its talking or secondary circuit to the line for operation.

698,887. DOUBLE-ACTING CYLINDER-PUMP. EMERY R. ANDERSON, Midland, Tex., assignor of one-half to Martin L. Tied, Midland, Tex. Filed Aug. 5, 1891. Serial No. 71,088. (No model.)

Claim.—1. In a double-acting cylinder pump, the combination with the piston-cylinder and the outer casing, said cylinder being provided with radial partitions dividing the casing into induction and suction chambers, transverse partitions closing the opposite ends of said chambers and dividing the upper and lower ends of said chambers respectively into auxiliary suction and induction chambers, an impervious transverse partition in the lower portion of the piston-cylinder, an apertured partition above the impervious partition, a check-valve disposed in the

lower end of the piston-cylinder and arranged to close its lower end, a check-valve arranged to seat on and close the apertured partition, a piston in the piston-cylinder, parts connecting the auxiliary induction-chamber with the piston-cylinder below, and transverse partitions, parts connecting the lower end of the piston-cylinder with the induction-chamber, parts connecting the latter with the piston-cylinder above the piston, parts connecting the piston-cylinder below the piston with the lower end of the suction-chamber, and apertured check-valves controlling the discharge from the upper ends of the piston-cylinder and suction-chamber, substantially as described.
